Somewhere, Over the Rainbow – Give Your Spectrum Its Wings With Our Graphic Utilities

Not Turtles Again! An All-In-One Logo Program

Zipping and Zapping With Short Routines

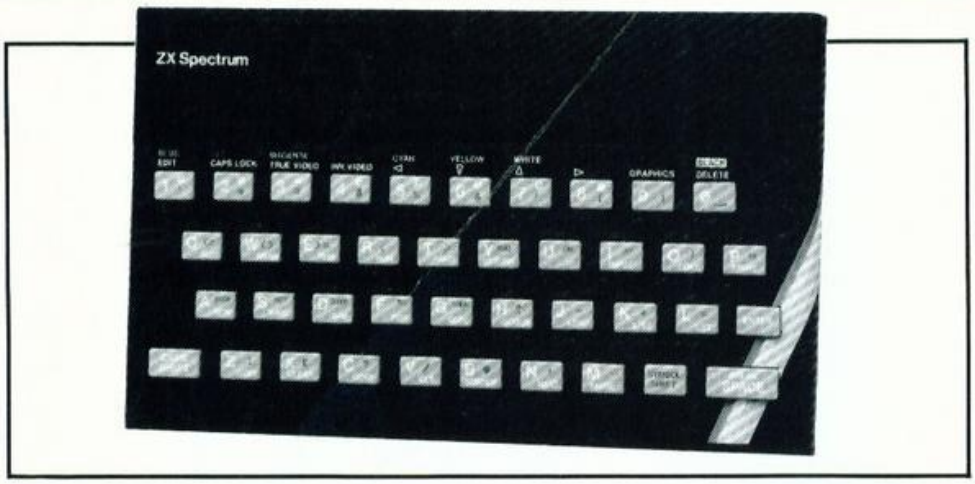
Compose Yourselves With Great Music Features

PLUS The Best Educational And Fun Spectrum Listings

Can You Handle The Galactoids?

Peeking about

Voyeurs will love this chance to PEEK into memory to sort out screen character positions.



The Spectrum is an interesting machine in many ways, but it has one characteristic which can be infuriating. Where a memory mapped display allows the character in a given screen position to be determined by a simple PEEK into memory, the Spectrum display store is arranged in what appears, at first sight, to be a totally chaotic manner, and PEEKs provide no useful information. The manual warns the user of this, and suggests the use of SCREEN$ as an alternative, but that is no use with user-defined graphics, which are seen as spaces.

A little patient experiment shows that the eight bytes forming the character at the top left hand corner of the screen are held in locations:

16384
16640
16896
17152
17408
17664
17920
18176

16384 is the start of the display memory area; and the other addresses are obtained by adding 256 successively. Ah! So we can write:

Address = 16384 + 256*(n−1) + 32*x + y = 16128 + 256*n + 32*x + y

Where the address contains the nth byte of the character in line x column y.

UNBLOCKING THE SCREEN

But this fails after eight screen lines have been examined. An entirely new block starts, 2048 locations after the first, and we have:

Address = 18176 + 256*n + 32*(n−8) + y = 17920 + 256*n + 32*x + y

After a total of sixteen lines, a third block starts, and we have:

Address = 20224 + 256*n + 23*(x−16) + y = 19712 + 256*n + 32*x + y.

AMUSING AND USEFUL

Input a number, and the screen fills with characters. Then a scan starts, in which the eighth byte of each character is compared with the number which was input. If the two are equal, the character is converted to reverse video by PRINT OVER. Otherwise, the character remains unaltered. Input zero, and most of the characters will change. Those which do not are characters with descenders, with at least one high bit in the last byte. Input 52, and p and q will be picked out. To save tedious experiment, the numbers worth trying are 0,6,8,16,24,32,56,60, 64 and 255...

The second input allows you to state a colour and then another check number, so that you can put a colour against a specific last byte. Not a particularly useful program, but quite amusing.

Now create some user graphics and extend the original program so that it prints them, by changing the 95 entries to 132. If you use a bit of craft, you can make the lowest line of each special graphic give a different number, preferably not one in the list given above. The program will then pick out this number, identifying each graphic individually.

It need scarcely be said that the byte examined need not be the last one forming the character. If the graphics make a different byte more convenient, all that needs doing is a change in BASE value.

At a guess, the SCREEN$ function may compare the bytes which it reads from the character with the character pattern data stored near the top of the ROM. It would be possible to perform the same trick with the special graphics data, but that would probably be an overkill. However, there may be cases which would make that worth while, though machine code would be necessary to keep the response time down.

```
10   INPUT N
20   LET A=0
30   LET B=INT (A/95):LET C=A-95*B
40   PRINT CHR$(C+32);
50   IF A<703 THEN LET A=A+1:GOTO 30
60   INK 2
70   FOR X=0 TO 21
80   FOR Y=0 TO 31
90   LET BASE=18176
100  IF X>7 THEN LET BASE=19968
110  IF X>15 THEN LET BASE=21760
120  LET D=(BASE+32*X+Y)
130  IF PEEK (D)=N THEN PRINT OVER 1; AT X,Y; "RV
     SP"
140  NEXT Y:NEXT X
150  INPUT M:INK M
160  INPUT N
170  GOTO 70
```

IQ TEST

If people tell you computing makes you dull and introverted, try this test to see if they are right!

This is a program for the 48K Spectrum. It contains a fifty question intelligence test and two short personality tests. The IQ test contains both verbal questions and mathematical ones. The maths questions can be worked out on paper (without the use of a calculator) and the results entered when prompted by the computer.

YOUR STARTER FOR FIVE

The listing may look very long, but don't be put off from typing it in, as many of the lines are very similar and can be edited out, altered and re-entered with a new line number. The tests can be seen in an example screen before use. However, the main IQ test is timed (via a real-time clock which is updated periodically), so you have a maximum of thirty minutes to complete the test.

You may pass on any question, by entering 0 to the answer(s). At the start of each loop you are requested to enter the number of the question that you wish to attempt. This allows you to return to any question you may have passed on. Please note that if you DO attempt a question, whether you get it right or wrong, you will not be allowed to return to it later. You are only allowed one attempt at each question.

SLOW BUT SURE

Take your time with the test and answer each question carefully, but don't spend too much time over a question you may be stuck on. At the end of the test, if the time is up, or you request question 0, or if all of the questions have been tried, then your score, your IQ rating, and some comments will be printed on the screen. You can then try to answer questions in the personality tests. These questions have no time limit, and you only have to enter A or B in answer to them. Don't think too hard about the questions, try to answer them instinctively. At the end of each of these questions a comment is made based on your results.

HOW IT RUNS

2	*POKE keyboard response time/sound. Define names variables for program size and free memory (in K).*
3-9	*Credits*
11-17	*Initialise screen picture (IQ Test). Each line entered as a string. The whole picture is then defined as the sum of these (F$). String is then printed on the screen.*
20-23	*Load machine background noise.*
25-30	*Introduction to program. The message is stored as Y$, then string-splitting is used to sequentially print this on the screen + background machine code noise & beeps. The speed is changeable by altering PAUSE 3.*
35-40	*Menu of choices. Input and go to line number.*
50-55	*Continue subroutine.*
60-65	*Start test subroutine.*
70-75	*Choose question number subroutine.*
80-86	*Check to see if question has already been answered.*
90-96	*Prevent a repeat of the same question.*
100-190	*Update the real-time clock (based on the FRAMES system variable), and print the time on the screen (00.00 to 30.00 minutes/seconds).*
200-250	*Initialise variables eg IQ,SCORE,MIN, SEC etc... plus start clock and test.*
300-360	*Double number answer. (X,Y)*
400-420	*Single number answer (X)*
500-520	*Single word answer.*
600-640	*Personality test (P.TEST) no. 1. Answer and score (A$,PT1A)*
650-690	*Personality test (P.TEST) no.2. Answer and score (A$,PT2B)*
700-730	*Load UDG. Graphic "A" = " "*
800-815	*P.TEST no.1 results/comments.*
900-915	*P.TEST no.2 results/comments.*
1000-1140	*IQ Test. Introductory message (Y$), as above. Start test, choose question number, update clock, check to see if question already answered, go to question line number (1000 + (16 * Question number)). The main question loop.*
1116-1910	*The 50 IQ test questions. Print question, GOSUB for an answer, check to see if question was passed on (answer = 0), remove question from screen, return to main loop (line 1040).*
1950-1990	*Time-up/test completed, GOSUB for results, return to menu.*
2000-2310	*P.TEST no.1. Set-up screen, and print intro message (Y$). Start test, print questions in sequence, check each answer, increase score. End test, GOSUB for result, print result/comments and return to menu.*
3000-3540	*P.TEST no.2. As per P.TEST no.1 except no message and there are 30 questions.*
4000-4230	*IQ test results. Get IQ value from score, print score, print IQ value and comments, return to menu.*
5000-5130	*IQ test examples.*
9990-9999	*Auto-save/verify routine: By GOTO 9900, and REM for program size: 34.6K.*

THE PRACTICE ELEMENT

It must be noted that IQ tests cannot be regarded as totally reliable, and that the test can only be used once on a given individual because of the practice element. However, an examination of the listing should provide some very useful routines which you could incorporate into your own programs. For example: The named size/free variables; the message routines and the real-time clock (based on the FRAMES system variable); and finally, the auto-save/verify routine which saves time during the development of any program.

Block Delete

Faster than many professional toolkits, this short utility allows easy deletion of blocks.

Most deletion routines only allow you to delete one line at a time; this one automatically deletes blocks as well as being quite short.

It is set up in the printer buffer and is therefore suitable for both 16K and 48K machines.

MONITOR ROUTINE

It calls the monitor routine at 6510h to get the address of the first line to be deleted and then again to get the address of the line following the last line to be deleted. These addresses are then passed to the monitor routine at 6629h, which performs the necessary deletion.

This produces a block deletion routine that is much, much faster than many professional toolkit programs!

IN FACTS

A few words on the IN function might be useful. When using this (except on issue 3 Spectrums) the value of BIT 7 is 1, which means the value returned as natural will vary between 255 and 191. Only the 5 least significant bits are relevant when testing for a key so:
LET X=IN 65022: LET X=X−32*INT(X/32).

Then test for lower values which will be the same regardless of whichever machine is being used by:
IF X=23 THEN...

HOW TO USE IT

The routine shown provides a simple, compact, easy to use way of deleting blocks of source lines from a BASIC program. To use it, key in the program and SAVE it. Lines 4 to 6 comprise the loader and data necessary to create the machine code. Key in 'GOTO 4 ENTER' and the machine code is POKEd into memory locations 23300 onwards (this is in the PRINTER buffer). If the flashing message 'Checksum error' is displayed, you have probably made a mistake in the DATA statement at line 6. Check it carefully, correct the error and key in 'GOTO 4 ENTER' again. When correct, the message "DELETE loaded" comes.

Now you can test the routine. Key in 'GOTO 1 ENTER' and the routine requests the line number at which you want to start to deleting. Key in '4 ENTER' and the routine will ask for the line number up to which you want to delete. Key in '6 ENTER' and the routine will delete lines 4 to 6.

You can now save the BASIC and m-c with the commands:

SAVE "delete"

and

SAVE "deletcode" CODE mem,20

Now you have a routine which occupies lines 1 to 3 of a BASIC program. To use it, make sure there are no lines 1, 2 or 3 in the program you want to edit. Key in:

MERGE "delete"

and the three lines of BASIC routine are merged with your program. Now key in 'GOTO 3 ENTER' to load the machine code. The routine will ask you which lines are to be deleted as already described.

There is no restriction on the line numbers which you enter, except that they must satisfy the tests in line 1. If you give a non-existent line as the start line, deleting will commence with the next valid line. If the last line number you give does not exist, deletion will include the last line before this number. This is the most compact way of using the routine. However, if you don't mind using more than three lines, you can do the following. Delete line 3. Change line 5 to 'GOTO 1'. Now the routine will initialise itself when you MERGE it and key in 'GOTO 4 ENTER'.

```
   1 INPUT "Delete from line ";f
;" to line ";t: IF f<3 OR t>9999

D. ROBINSON

Redefinition

Use graphics that you've redefined in your own programs.

This program allows you to redefine 1152 graphics in blocks of 96 for use in your own programs. The data can be stored on tape and re-loaded whenever you require them. The graphics can be called up by POKEing the CHARS. system variable 23607.

POKEing RAM

The data for the standard character set are POKEd into RAM and are then read from ROM locations 15616 to 16383. The character set can then be redefined in RAM and called into the program by POKE 23607, N where N is the start address of the newly defined set minus 256 and divided by 256. The first address of the graphics is 50432 leaving more than 27K of RAM for your own program plus the user defined graphics area.

FACILITIES

There are four facilities: character redefiner, with complete instructions and two grids so that one graphic can be compared with another; loader; saver and set call up. In the latter the redefined set appears in the program itself. Instructions are given in the program.

HOW IT RUNS

1-200	*Explanation*	*1000-1730*	*Define mode*
200-230	*Character set read from ROM to RAM*	*2000-2070*	*Load mode*
		3000-3050	*Save mode*
240-260	*Facility menu*	*4000-4030*	*Set call-up*

DAVID NOWOTNIK

Slogo

A BASIC simulation to introduce you to the world of Logo.

The aim of this article is to introduce the programming language of LOGO. I'm sure many readers will want to try LOGO on their Spectrums. But, if you've tried to find some commercial software which allows you to use LOGO then you might well have been disappointed; there isn't much available. As a remedy to that situation, I shall be presenting, in three parts, a BASIC program which simulates LOGO.

PART THE FIRST

In each part, you'll get a BASIC program to type into your Spectrum, and instructions on how to use the program. And, in using the program, you'll be using LOGO. So, by the time the series is complete, you should have a good understanding of the language. The program I'll be presenting later must be added or MERGed to program one, then the third added to the other two. So, while this first program will fit a 16K Spectrum, you'll need a 48K Spectrum to accommodate the final version.

Ideally, a LOGO translation program should be written in machine code for a fast operating speed. I've written my version in BASIC as it's easier for me to write it, and easier for you to type in. But in using BASIC, speed is lost — that's why I've called my version of the language SLOGO!

Once you have entered the first listing and SAVEd the program on tape, you are ready to start. But before we begin typing in our LOGO commands, it might be useful to consider the background and principles of this language.

LOGO THEORY

LOGO was designed to provide children with an early introduction to computer programming and to develop their abilities in logical thinking. The commands of LOGO are simple to understand, yet LOGO encourages a good programming style by virtue of its structure. LOGO is best known as a graphics language, enabling still (and animated) pictures and patterns to be drawn. More powerful versions for text handling as well as graphics but my version, in common with most, deals with graphics only.

You'll find LOGO a very useful language if you have young children, if you want a versatile graphics routine or if you want to move on from BASIC, LOGO is an easy language to learn, yet it introduces you to structured programming, as used by more powerful languages such as FORTH.

TURNING TURTLE

Drawing with LOGO makes use of a turtle — but before you rush off with complaints to the RSPCA, these are only imaginary animals! Imagine you had precise control over the movement of your turtle; instructing it to go forward or back, turn left or right, all by specific amounts. Your turtle carries a pen which you can instruct to be lowered onto a sheet of paper, so that, as the turtle moves, a line is drawn. Using combinations of the four movement commands (forward, back, left and right) drawings and patterns can be created.

Some versions of LOGO actually make use of a robotic 'turtle' which is interfaced to a computer. LOGO commands are transmitted through to the turtle, creating shapes on a sheet of paper placed on the floor. More often, the monitor or TV screen forms the paper and an electronic turtle is drawn and moved, on the screen. This is how my version works.

LISTING 1

Enter Listing 1 and then RUN the program and you'll see the turtle on the screen. It is represented by the "^"; the point is its head and this indicates the direction of the turtle. You'll see that the turtle's starting point is at the centre of the screen, heading directly up the screen.

At the bottom of the screen you'll see "W;" and a flashing cursor. This tells you that the computer is waiting for you to enter a command. At this stage, this LOGO program will accept only 8 commands as shown in Fig.2. Note that all commands are entered in capital letters (CAPS LOCK mode is automatically set by the program) and for some commands, a two letter abbreviation can be used instead of the full word. Before you use any command, I'll describe what each one will do.

LET'S GO

Now let's try a few examples. Type in:

FORWARD 40 (or FD 40), and press enter. You'll see the turtle disappear, a line 40 pixels long will be drawn, and then the turtle reappears. To enable the program to work as quickly as possible, our turtle will always disappear when all instructions are complete and the "W;" symbol comes back on the screen. Also, notice that when the program starts, the pen is in the down position, enabling a line to be drawn.

Now, lets turn the turtle 90° to the right. Type in:

RIGHT 90 (or RT 90) and press enter.

Then move forward again:

FD 40.

If you continue entering alternatively RT 90 and FD 40, you would end up with a square. As it is cumbersome to type in one command at a time, LOGO allows you to string commands together. Let's see how. First, clear the screen, and reset the turtle using the command DRAW, then enter:

FD 40 RT 90 FD 40 RT 90 FD 40 RT 90 FD 40 RT 90 and enter.

Leave a single space between each command and number. This, again, draws a square. You may have noticed that we are repeating the same two commands four times. Fortunately, LOGO allows repetition of commands to be simplified and it's one of the things I'll be dealing with later.

OFF SCREEN

What should happen if the turtle goes off the screen? Let's find out. ▷

Clear the screen with DRAW, then enter:

RT 10 FD 2000.

The turtle is turned slightly to the right, then moves forward 2000 pixels. As it disappears off the edge of the screen, our turtle reappears on the other side. This feature is called wrap. It is useful to draw special patterns and means that you won't get an error message if you accidentally go off the edge of the screen.

Another feature of this LOGO program is that the specified number used by FORWARD, BACK, RIGHT and LEFT can be replaced by a random number. As an example, try:

FD RANDOM 50

The turtle will move forward by an amount somewhere between 0 and 50.

That's enough of the theory of LOGO for now. Try making up some drawings, patterns, or shapes for yourself. The program has an error trapping routine, so if you make a mistake, you should get a reasonably friendly error message. In the next part, you'll notice a quantum leap in the power of this LOGO translater.

PART THE SECOND

I'll now expand the number of instructions you can give to the turtle, turning this program into a quite powerful and versatile version of LOGO.

Take a look at the table, which gives you a list of all the extra LOGO commands that will be introduced to you in this section. But before you can get the program in part one to accept any of these new commands, you'll have to add the second program lines to those of the original program. Here is the best way of doing that:

ADDITIONAL LOGO

First type into your Spectrum the program lines. Then, save this routine on tape. Load into your Spectrum the program I gave you earlier and MERGE in the new routine just saved on tape. This may seem a complicated way of adding these new lines, but it will help if you have made any mistakes in typing in.

If you find your expanded program does not work smoothly, then check through your second program — it should match exactly the listing. As I warned earlier, the merged programs will only fit a 48K Spectrum, so I'm afraid you'll only be wasting your time if you have a 16K machine.

EXTRA STUFF

When you RUN the program, you should get the same response as before; a "W;" prompt message at the base of the screen, and the turtle ("A") at the centre of the screen. If you can recall, we have already used the commands FORWARD, BACK, LEFT and RIGHT to move the turtle, and DRAW, HOME, PENUP and PENDOWN as additional control instructions. Let's have a look at the first six of the new instructions, which also happen to be the simplest.

So far, all our drawings have been made using black 'ink' on white 'paper'. The command PENCOLOUR (or PC) allows you to change coours at anytime. To complete the PENCOLOUR command you have to add a number, 0 to 7, according to the number keys on your Spectrum. For example, PENCOLOUR 1 will change the foreground colour to blue for subsequent movements of the turtle.

I have already introduced the concept of wrap. This is when an instruction to the turtle causes it to 'fall off' the edge of the screen. with wrap, the turtle will re-appear on the opposite side of the screen, and continue on its way. You can forbid the turtle wrap round using the command NOWRAP. After using NOWRAP, if you accidentally command the turtle to go off the edge of the screen, you will get an error message. To reinstate the wrapping facility, use the command WRAP.

SET IN YOUR WAYS

The last three instructions of the first group are very sraightforward. COPY will produce a copy of your screen display on the printer, SAVE allows you to save the program (I will deal with creating a LOGO program soon) on tape, and STOP simply stops the LOGO program, and hands you back to BASIC. Remember with all LOGO commands to type them out in full (do not use the equivalent BASIC keywords — LOGO won't recognise them), or use the two letter abbreviation, if one is available.

The next group of instructions all start with SET, and they move the turtle in a precise way. If you look in your Spectrum handbook (on page 121) you'll find out how high resolution graphics are created. There are 176 dots from top to bottom of the screen, and 256 from left to right. Each one of these dots can be defined by a co-ordinate (like a place can be fixed by a map co-ordinate). The dot at the bottom left of the screen has the co-ordinate 0,0 and the one at top right 255,175. If you move vertically up or down the screen, you are moving horizontally left and right, you move along the x axis.

SETX APPEAL

All that may seem horribly mathematical, but I hope it will be clearer when we use the SET instructions to move the turtle from wherever it is SETX will move the turtle along the x-axis (horizontally left or right) to a specified point. Thus, SETX 10 will move the turtle from where ever it is on the screen horizontally to a point which is 11 dots (remember the first has the number 0) from the left hand edge of the screen. Similarly SETY 10 will move the turtle vertically to a point 11 dots from the bottom edge of the screen, not counting the command line. If you move the turtle with the pen down, a line will be drawn. Try this example. Reset the turtle with the DRAW instruction, then enter the command:

SX 60 SY 140 SX 128 SY 88 (and press ENTER)

This will draw horizontal and vertical lines to create a rectangle.

The command SETXY will move the turtle to the coordinates specified after the command. You'll need two numbers after SETXY, the first is the x-coordinate, the second, the y-coordinate. For example, with the rectangle from the above routine still on the screen, enter:

SETXY 60 140 (or XY 60 140) and press ENTER

This will draw a diagonal to the rectangle, taking the turtle to the coordinates 60, 140 which is one corner (the top left corner) of the box.

Try a number of SETX, SETY and SETXY instructions for yourself. The X number must be between 0 and 255, and the Y number between 0 and 175.

DIRECTION

You may have noticed that, in using these SET instructions that the turtle's direction (or heading) is not changed from that before the SET instruction was used. There is an additional instruction to alter the heading of the turtle to a definite direction; this is the SETHEADING command. SETHEADING 0 will direct the turtle to point vertically up the screen; SETHEADING 270

will point the turtle horizontally towards the left edge of the screen. The heading you give to the turtle must be between 0 and 360.

If you are getting confused between the SETHEADING and LEFT and RIGHT commands then remember, SETHEADING gives you *absolute* command of the heading whereas LEFT and RIGHT turn the turtle *relative* to the turtle's direction. ▷

One final piece of theory for this part before we try a few more examples. If you remember we created a square with the instructions:

FD 40 RT 90 FD 40 RT 90 FD 40 RT 90 FD 40 RT 90

You have probably noticed that the two commands FD 40 and RT 90 are repeated 4 times. There is a command in LOGO which helps in repetition. Quite logically that command is REPEAT (RP for short), Here's how it is used in drawing a box. Clear the screen with the DRAW command, then enter the command:

RP 4 (FD 40 RT 90) and press ENTER

The number after REPEAT (or RP) is the number of times the commands within the square brackets are to be repeated. Remember, always leave a single space between commands, numbers, and square brackets. To be complete, the REPEAT command, *must* be followed by a number, then an 'open' square bracket. A 'close' square bracket indicates the end of the repeat loop.

NESTED LOOPS

In the same way that FOR-NEXT loops can be 'nested' in BASIC, so can REPEAT loops be nested. As an example, the following LOGO instruction will produce a symmetrical pattern.

RP 12 (RT 30 RP 8 (RT 45 FD 20))

Nesting of loops is easier in LOGO than in BASIC, and as long as you have the same number of "("as")", then you shouldn't go too far wrong!

The above command can be quite simply varied to produce a variety of symmetrical shapes. If you look at the command, I've linked together (under the command) two sets of two numbers. If you multiply the first two together you should get 360, and if you multiply the second you'll also get 360. And that is the trick in getting symmetrical patterns. You can replace any pair of numbers with another pair, so long as the new numbers in the pair, when multiplied together, produce 360. Why not try a few, and see what shapes you can produce.

Here are 3 other pattern drawing routines you may like to try:

DRAW RT 20
RP 5 (FD 40 RT 135 FD 40 LT 63)

DRAW PU XY 80 60 PD
RP 8 (FD 40 RT 45) RT 45
RP 8 (FD 96 RT 135)

DRAW PC 1 RP 3 (FD 40 RT 120)
PC 2 RP 3 (BK 40 LT 60)
LT 90 PC 3 RP 3 (FD 40 RT 120)
PC 4 RP 3 (BK 40 LT 60)

Type in one line at a time, pressing ENTER when you get to the end. Try and follow what is happening on the screen, and relate it to the instruction you have just entered. You'll find that you should soon understand most of the LOGO commands I've introduced so far.

STORAGE

Up till now, we have simply entered commands to the computer, and the Spectrum has obeyed them immediately, then the command is forgotten. It would be far more useful for the computer to store instructions and allow us to recall them at will. Our LOGO translater will then be operating on a LOGO program.

PART THE LAST

To incorporate the program in this section with the version you completed last time, first enter the listing into your computer, then store it on tape. Then, load into your Spectrum the program completed last time (from parts 1 and 2), then MERGE this program into it. Finally, save a copy of the completed program, then you're ready to RUN.

NEW COMMANDS

There are two additional commands

```
Definition - SKY

Ø  BG Ø Ø 31 5 5

Definition - SUN

Ø  PU XY 4Ø 16Ø PC 6 PD

1  SX 42 PU XY 38 159 PD

2  SX 44 PU XY 37 158 PD

3  SX 45 PU XY 37 157 PD

4  SX 45 PU XY 38 156 PD

5  SX 44 PU XY 4Ø 155 PD

6  SX 42 PU

Definition - GROUND

Ø  BG Ø 6 31 14 4

Definition - HOUSE

Ø  BG 2Ø 1Ø 5 5 2

Definition - DOOR

Ø  BG 22 13 1 2 1

Definition - WINDOWS

Ø  BG 21 11 Ø Ø 7
```

created by the extra routines in this part. The first is BACKGROUND (BG), which allows you to define the paper colour in specified areas of the screen. Five numbers are required after BACKGROUND to complete the command. Here is an example which you can try:

BACKGROUND 0 0 31 6 5

The first four numbers define the area, a rectangle, to be "painted", and the last number is the colour (0 to 7, as shown on the Spectrum keyboard). The first two numbers are the x and y co-ordinates of the top left point of the area to be coloured. In the example, 0 0 refers to the top left of the screen, unlike the co-ordinates for SET which start at the bottom of the screen. In fact the first two BACKGROUND co-ordinates are the same as the BASIC PRINT AT. The third and fourth numbers of the BACKGROUND command are width and height of the square to be coloured. In the example the number 31 is the full screen width, and the number 6 means six character squares down. The number 5 is the colour cyan, and so, the example given will "paint" a cyan block at the top of the screen. In an example later on, the same command will create the sky in a scene which will be created with LOGO commands.

The other new command in this part is LIST. It will list to screen or printer a LOGO program. But, as I haven't yet explained how to create a LOGO program, you won't yet have anything to list!

```
1  BG 24 11 Ø Ø 7

Definition - ROOF

Ø  PU XY 16Ø

1  96 PC Ø

2  PD SH 45 FD 33 RT 9Ø FD 33

Definition - SCENE

Ø  SKY SUN

2  FD 2

3  RT 9Ø FD 3Ø LT 9Ø FD 1

4  LT 9Ø FD 3Ø RT 9Ø FD 1

5  RT 9Ø FD 3Ø
```

DEFINING LOGO COMMANDS

LOGO programs are made by creating new commands from the commands that LOGO already understands. You create a new command using DEFINE (DF). Most versions of LOGO use TO instead of DEFINE, but I've used the latter as it is more explanatory. You complete the DEFINE command with the new command name, which must be different from all the commands currently available to LOGO. As an example, let's tell the computer how to draw a box; we'll define a command called BOX. First enter the command:

DEFINE BOX (or DF BOX)

The screen will clear after the computer has checked that the command BOX doesn't already exist. You'll get the message 'DEFINE BOX' at the top of the screen, and the usual 'W;' at the base of the screen.

There is no standard way of defining new commands in LOGO; there are probably as many different ways as there are versions of LOGO. So the instructions that follow just happen to be the way I have decided to allow the definition of new commands.

To define our box, enter the command:

RP 4 (FD 40 RT 90)
and press ENTER.

That line will appear at the top of the screen with a line number of zero. The line number is not used by LOGO; I've just added it to identify lines in case we want to make any changes. In any one definition, you can enter up to 10 lines, but no line can be longer than 20 characters. For our BOX definition, all we need is the one line already entered, so we tell the computer we've finished by entering END. You'll get a message to tell you that the new command BOX has been stored, then you're back to a clean sheet of paper, and the 'W;' symbol. The LOGO program will now accept BOX as a command; try it!

You can include in your definitions already defined commands. As an example, define another command PATTERN, as follows:

DEFINE PATTERN
RP 8 (BOX RT 45)
END

When complete, enter PATTERN as a direct command; you'll get a pattern based on the BOX routine you defined. ▷

Now define MOVE:

```
DEFINE MOVE
PU XY 50 PD BOX
PU SX 120 PD BOX
PU SX 190 PD BOX
END
```

Define the command as before, then enter MOVE as a direct command.

EDITING COMMANDS

The pattern created by PATTERN wasn't particularly exciting; we could change PATTERN to improve it. To do this we use the command EDIT. The syntax is EDIT PATTERN. Once you have entered this command, the computer will spend a few moments searching for PATTERN, then reformatting, ready for changes to be made. The definition will reappear on the screen as you entered it (apart from END). At the bottom of the screen is a menu of editing options.

- Option 1 is EDIT. It will allow you to change a line. Enter the line number of the line you wish to change, and re-enter the line as you want it.
- Option 2, INSERT allows you to insert another line between two lines of the screen. Remember, you cannot exceed a total of ten lines, so you can insert a line if you have 9 lines or less in your definition. If you opt to insert a line, say number two, then the previous line two becomes number 3, 3 becomes 4, and so on.
- DELETE (option 3) allows you to delete a line.
- REMOVE (option 4) will remove the whole definition. Pressing 5 will return you to normal command ('W:').

So, to EDIT the command PATTERN, you will want to change line zero. Press 1 to get the EDIT option, and press 0 to indicate that it is line 0 which you want to replace. Then enter:

```
PR 12 (BOX RT 30)
```

Press 5 to exit the edit routine, enter the direct command DRAW to clear the screen and reset the turtle, then try PATTERN again.

LOGO STRUCTURES

By now you should already have an ideal of how programs are built up in LOGO. Each definition should be quite independent; you should check it out before moving on to the next definition. This is structured programming. It has the advantage of being easier to follow what is happening (than, for example, 'unstructured' BASIC), so it should be easier to correct any mistakes. Programs written in this way are also much easier for others to understand. The BBC machine's PROCEDURE and the QL's DEF PRO also allow programs to be structured in a similar way.

To start you off in LOGO programming look at the listing, obtained by the LIST command. When entering a LOGO program, remember to enter one definition at a time (end each with END, which is not shown in the listing), then test it and edit as necessary before moving onto the next. In the example program, notice that the command SCENE is the command which uses all the other commands in its definition. It is the command which is central to the operation of the program; you operate the whole program (when it's all in the computer) by entering the direct command SCENE. In this way LOGO differs from BASIC. Its programs will not start with a single RUN command; they start with a defined command which is the 'core' of the program.

There is more to LOGO than the aspects I have covered in this series.; LOGO also uses variables; it allows decision making with IF...THEN ...ELSE structures; and it permits text handling. If you want to know more about LOGO there are several good books available (for example LOGO Programming by Peter Boss). Despite the limitations of my program, I hope you have gained an insight into the fascinating possibilities that LOGO is able to offer as an introduction to programming to young and old, or simply, as an easy to use graphics creation package.

COMMANDS

HOME	*This moves the turtle from anywhere on the screen back to its starting position at the centre of the screen, heading directly up the screen.*
DRAW	*This clears the screen, then moves the turtle HOME.*
FORWARD	*The turtle is moved forward a specific amount. To complete the command, you have to tell the turtle how far to move forward, eg FORWARD 20 (or FD 20). The unit of distance is one pixel; remember the screen is made up of 256 pixels across, and 176 down.*
BACK	*The turtle is turned head-to-tail, then moved in the same way as FORWARD (eg BACK 25).*
LEFT	*The turtle's head remains in the same place but its body will swivel so that its direction rotates to the left. You have to tell the turtle how far to turn. As do FORWARD and BACK, the command LEFT requires a number added to it to complete the instruction, to tell the turtle how much to turn. This number is the angle of turn in degrees. If you've forgotten that 90 degrees makes a right angle, then using Fig 3 as a guide when using the left (or RIGHT) command. Angles should be whole numbers between 0 and 360.*
RIGHT	*This is the same principle as LEFT, but, of course, the turtle turns right instead of left.*
PENUP	*This command raises the pen from the paper so that the turtle can be moved without a line being drawn.*
PENDOWN	*The pen is placed on the paper.*

GAVIN SMYTH

Galactoids

A fast moving machine code game — can you blast the random coloured spider-like aliens before it is too late?

At last! A program that overcomes the problem of the speed (or lack of it) of Sinclair BASIC. This machine code space invaders-type game occupies just over 1K and so will run on either the 16K or 48K Spectrum. This is not an attempt to teach machine code programming, but with the instructions given, anyone can run the program without having to understand it.

The object of the game is to destroy the eight coloured spiderlike aliens randomly moving about the screen dropping bombs all the time. Naturally you have to hit them dead centre, but if a bomb touches your gun at all, bang! If you are invaded, you only lose a life, not the whole game. To begin with, the game is easy since the gun moves at eight times the speed of an invader but after you have bumped off the first three without trying, the remaining aliens move at a fifth of the guns speed — to get the last one, you have either to be pretty quick or very lucky! After this, you get another sheet with an extra life, but games do not normally last for more than three screenfuls of aliens.

THE AIM OF THE PROGAM

There are several reasons for writing this program:

1 To make a game less predictable than the familiar legions marching across the screen in neat rows. This randomness adds to the difficulty, keeping games short and defeating those show-offs who hog the space invaders machine all evening.

2 To keep kids (and adults) out of the way by making the games colourful, noisy, simple to operate and totally uncrashable (famous last words). The controls are: Z for left, X for right and space to fire. There is no return to BASIC in the program (to prevent cries of "Hey! They've stopped moving!"), so the only way to dispel the menace forever is to pull the plug out — but beware, the game is addictive.

3 To cause endless frustration with the aliens' continuous chirping and high scores not even in three figures. (My best so far is a mere quarter century and the score counter can clock up to 9999.)

4 Finally, to show how the Spectrum ROM can be used to simplify programming be performing the more fundamental duties such as printing.

INTERESTING ROUTINES

Here are a few of the techniques used in the program to get a lot out of the machine without typing too much in:

RANDOM NUMBERS: The subroutine RND (address 32056d) returns a fairly random number in the A register. What it does is step a pointer through the ROM and return the value of that location (random enough for this purpose although there is a distinctly non-random region) an unused region of over 1K starting at 14446d, where all the memory locations contain 255d. This provides an interesting short period every three sheets or so when the aliens move uniformly without dropping bombs and with a distinct sound, but they are still just as frustratingly tricky to hit.

SOUND: The subroutine BLEEP (31677d) is used to emit a random short tone. It is there simply to slow the program a little, it can be slowed still more by increasing the value of DE in this routine (equivalent to POKEing a larger number of locations 31683d). This routine calls the ROM subroutine BEEPER (969d) which controls the loudspeaker. This is one of the few routines that corrupts the IX register pair, hence the PUSH IX and POP IX near it in the program in places.

To use BEEPER, DE should contain a number equal to INT(frequency*duration) and HL should contain INT(437500d/frequency- 30.125d). For example, to play the note A 440Hz for 2.5 seconds:

DE contains INT(440*2.5)=1100d
HL contains INT(437500/440-30.125)=962d

INVADER CONTROL: The IX register pair is used to hold the start of the individual invader database, greatly simplifying code since, for example, the invader column is always (IX+1) regardless of the invader being used.

GRAPHICS GALORE

The remainder of the routines deal with graphics:

CLS (3435d): This routine simply clears the screen.

BORD1 (8859d): This sets the border to the colour contained in the A register. For example, to set a red (code 2) border:

```
LD A,2
CALL BORD1
```

CHANOPEN (5633d): Before writing to the screen, it must be opened for printing. The upper screen is channel "S" with code 2, so to prepare for printing:

```
LD A,2
CALL CHANOPEN
```

PRSTRING (8252d): This prints a string of characters of length BC which starts at the address contained in DE. For example, to print the word "Sinclair" which is held in the ROM at 5440d:

```
LE DE,5440d
LD BC,8; length of word
CALL PRSTRING
```

OUTNUM1 (6683d): This routine prints out the integer contained in BC, it is used to print line numbers. The number must be positive and less than 10000.

(No check has been made for overflow of this type since it is unlikely that such a score will be reached.)

CLSET (3545d): There are two ways to move the print position. One is to use the AT code (22d) followed by position with PRSTRING or RST 10. This method is used in the PRINT routine, address 32034d. The other method is to use CLSET: for this, B contains 24d-row; C contains 33d-column. For example:

```
PRINT AT 5,6;is equivalent to:
LD B,19d ;(24-5)
LD C,27d ;(33-6)
CALL CLSET
```

You will notice that RST 10 occurs frequently in the program — this calls the main printing routine which displays the character with code held in A. It will cope with any character, including tokens, paper and ink controls, and position controls. For example, print blue "X":

```
LDA A,16d;INK control code
RST 10
LD, A,1 ;colour code for blue
RST 10
LA,88d ;code for "X"
RST 10
```

The subroutine MAININIT (31206d) takes care of setting up some system pointers:

UDG: Rather than move all the data for the graphics characters into the user defined area, the program changes the system variable UDG (23675d) to point to the graphics data at the end of the program. (If Mohammed can't come to the mountain. . .)

ATTRP: Loading location 23693d with 7 is equivalent to PAPER 0: INK 7. In general, this system variable contains:

FLASH*128d + BRIGHT*64d + PAPER*8 + INK

MASKP: Loading 23694d with 255d is equivalent to INK 8: PAPER 8: FLASH 8:

BRIGHT 8 — setting ink and paper to transparent so that screen colours will not be affected by anything printed — the alternative to this would be complex colour controls before each print.

There is also a general listing of the whole program (see listing 4).

Most of the information on ROM routines was found in Dr Ian Logan's book, *'Understanding your Spectrum'*, which contains a lot of valuable information on other routines and machine code for the Z80.

TYPING IT IN

We received the listing of this program in full HEX, Mnemonics and REM form-unfortunately this ran to 16 pages! The present form was obtained by a program which created the lines in listing 1 by PEEKing at the code from the tape of the program supplied.

Each line of the listing consists of ten DATA bytes plus a checksum to help ensure that errors are elminated. The method of entering these codes are slightly different for the 16 and 48K Spectrums:

48K: Enter both lisitings 1 and 2a and RUN the program, correcting any errors that are reported. Should you get an 'integer out of range' report, type PRINT i-50990 and press Enter.

PROGRAM STRUCTURE

START	*Call MAININIT*	*:Set system variables, 'random number pointer.*
NEWG	*Call NEWGAME*	*:Reset score(0), lives(4); print instructions; wait until ENTER is pressed.*
SCREEN	*Call SETUP*	*:Print score, hiscore, lives; set screen attributes (in bands of different inks).*
MAINLOOP	*For each invader — Test lives; if none, GOTO ENDGAME. If invader pointed to is dead, try next; GOTO MOVE8.*	
Call UPDATE	*:Call MOVINVDR*	*:1 in 16 chance of row change (¼ up, ¾ move down). Check limits; if on edge or top, restore old position. If on bottom, return from MOVINVDR. If on edge, reverse direction. Random 1 in 16 chance of reverse. If bomb not dropped, ½ chance of drop; copy invader position into bomb.*
	Call INVDRPRNT	*Erase old invader, print new one.*
	If bomb dropped, Call MOVBOMB	*:Erase old bomb; move down a row; print new bomb.*
	Call KEYBOARD	*:Call BLEEP. If SPC pressed and bullet not fired, copy gun position into bullet. If Z pressed, move left. If X pressed, move right. If new position out of range, restore old co-ordinates.*
	Call GUNPRINT	*Erase old gun, print new one.*
	If bullet fired, Call MOVBULLET	*:Erase old bullet; move up a row; If at top row, reset bullet else print new bullet.*
For each invader		
CHECK	*If alive, Call LASTROW*	*:If invader on bottom line, blow up gun and invader.*
.Call HITINVDR	*:If bullet and invader co-incident, Call BLOWNINVDR*	*:Explosion (flashing, beeping), Reset bullet; signal dead invader; decrease number :invaders; increase score; update hiscore if necessary; print score and hiscore.*
Call HITGUN	*:If bomb has hit gun, Call BLOWGUN*	*:Explosion; reset bullet; decrease lives; print lives.*
	If bomb is on bottom line, Call ERASEBOMB	*:Erase bomb; reset its co-ordinates.*

Loop back to CHECK for next invader.
Loop back to MOVE8 until all 8 invaders updated.
Go back to MAINLOOP to repeat sequence.

ENDSCREEN	*Award extra life; beep low tone; start another screen by jumping to SCREEN.*
ENDGAME	*:Call DISPLAY print end message; flash screen and beep; beep very low tone.*

Start another game by jumping to NEWG.

Correct any errors then NEW the program and enter:

```
10 CLEAR 30999: FOR i=31000 TO
32417: POKE i, PEEK
(i+20000):NEXT i
```

Now RUN it and enter Listing 3.
16K: Do not enter listing 1 but enter listing 2b and RUN the program, enter each of the 11 numbers in each DATA line one number at a time. If you make a mistake the program will tell you and you will need to re-enter that line.

SAVING

Before testing the program it MUST be saved on tape. Even though we have taken great pains to foolproof the entering system, it is still possible for an error to slip through!

First, remove the BASIC listing (it you entered it in the 48K mode make a copy on tape just in case by using NEW — the machine code is quite safe) then enter listing 3. To save both the loader and m/c enter GOTO 40, start the tape and press any key. After a few seconds the "start tape" message appears again, press another key and the m/c will be saved. Verify both sections by VERIFY"" and then VERIFY""Code.

To start the game either reload it from tape or enter RANDOMISE USR 31000. If all is well the instructions will be displayed and look out!

If it crashes then switch off, enter listing 4, RUN, reload the program and check each number until you find the mistake (not forgetting to ignore the last number of each DATA line), POKE the address given with the correct number. Now follow the saving procedure again.

Datafile

A multi-purpose file handling program with, er, multi-purpose file handling applications.

Keeping records can be a laborious job — bits of paper, alterations, amendments etc etc. But now in this comprehensive and versatile program you have all the facilities that most filing applications will require.

Datafile impressed us in both operation and in programming techniques, it is liberally REMmed so that the operation of each section is explained and has been well documented by Nigel for the operator to use.

Whatever your interest, job, or need, Datafile will be of use. Type it in and then read the following instructions on using it.

RECORD LIMIT

Datafile is a utility program which sets up a file in A$ in accordance with parameters supplied by the user. The only limit to the number of records held is the size of memory of your Spectrum. A 16K machine can only manage 28 records 100 characters long but fields within each record can be any length and each field can be given a name up to 6 characters long.

TOOLKIT

Toolkit is a set of subroutines designed to enable you to use files generated by Datafile in your own programs. The sample application program Letters gives an example of one such application.

The uses of these routines are manifold. You might use them to set up a directory of your records and tapes or books. You could equally use Datafile to keep track of all your business clients. The example which follows guides you through every stage of datafile and explains the use of Toolkit routines.

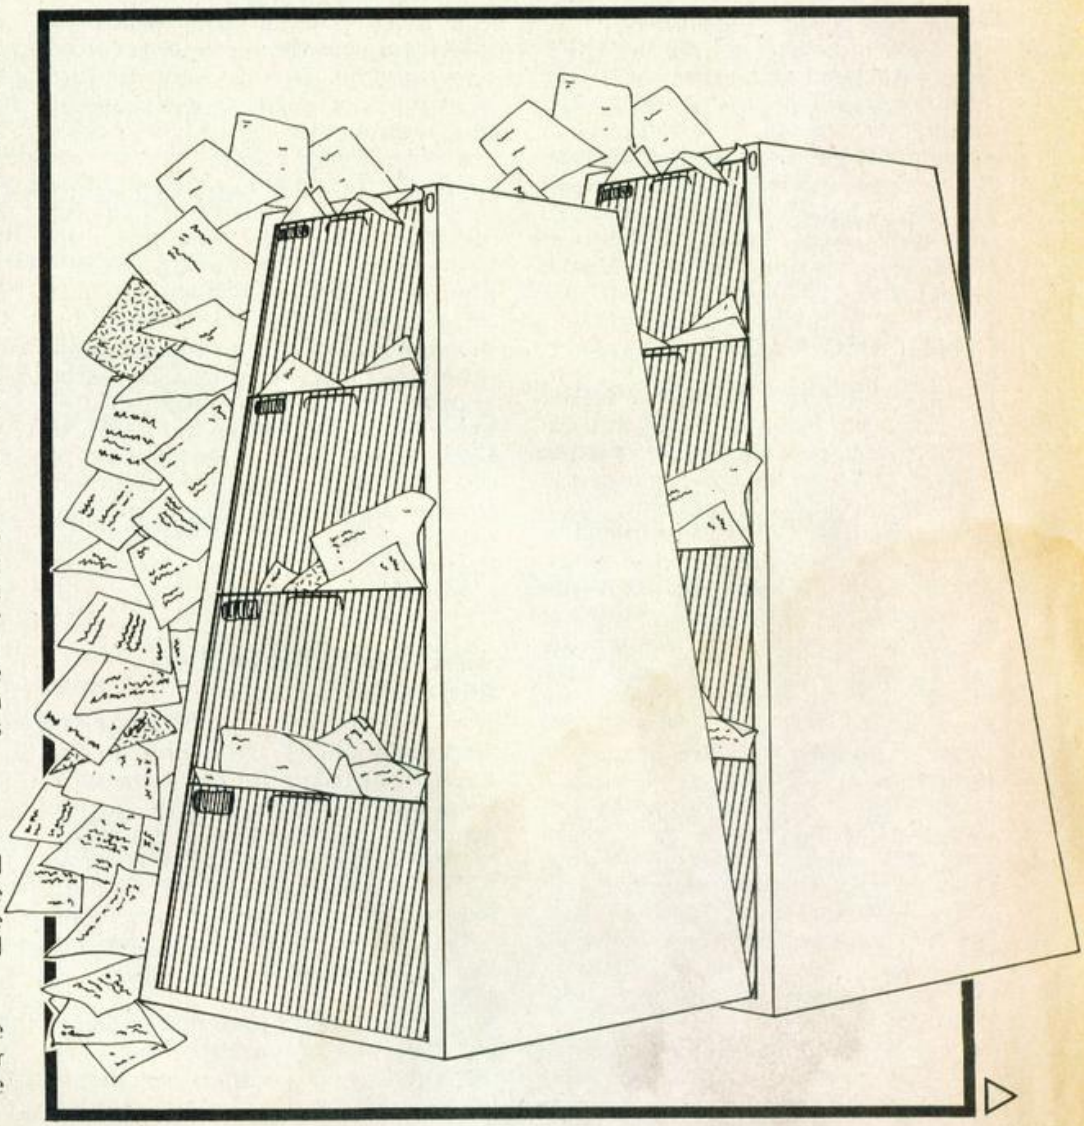
USING THE PROGRAM

On using the LOAD "" command and playing your tape you will be greeted with the main menu. Before you can use a file it must be defined in the following ways:

1. Select option from the menu. The program first asks you to name your file. You can call it anything you like but for this example enter CLIENT.
2. Number of records. Once you have named your file the program asks you how many records will be on this file. It is always a good idea to specify more than you think will be required to allow for future growth. For this example enter 10. This will mean that only 9 clients can appear on the file because Datafile uses the first record to store information about the file size and structure.
3. Record size. Each record can be any size you wish. Obviously it must be equal to or greater than the maximum number of characters of data what you wish to store on each record. For the example enter 120.
4. Number of fields. What you enter here requires some thought. It is necessary to define one field for every item of data which you want to hold on each client. The difficult part may be deciding what constitutes an "item of data".

Say you wanted to store the address of each client. You could specify just one field say, ADDRESS. This would not be very useful because then you would be unable to access individual lines of the address. A better solution would be to define one field for each line of the address and call them something like ADLIN1, ADLIN2 etc to refer to address line 1 and so on. For this example enter 10.

5. Field definition. If you have followed the example instructions then the program will now tell you that the CLIENT file has 10 records of 120 characters each.



MEAN IT

The program will then ask for a name and size for each field in turn. You can call the fields anything you like but any name more then 6 characters long will cut short automatically. I recommend that you give meaningful names to your fields to make future use of your files easier. There is no restriction on the length which you specify for each field providing that the sum of the field lengths is less than the record length which you entered at 3 (record size) above. For the example I suggest that you enter the following field names and lengths:

Name of field	Length of field
INITS	*6*
NAME	*15*
ADLIN1	*20*
ADLIN2	*15*
ADLIN3	*15*
ADLIN4	*10*
PHONE	*15*
ACCNO	*6*
INVDAT	*8*
INVNO	*6*
	116

The total length of these fields is 116 characters which is less than the 120 character size which we entered at 3 above, When you have entered the data above you will have defined all of the 10 fields which you specified for each client record at 4 above, You will now be returned to the main menu.

ENTERING DATA

First select option 2 from the menu. If you have been following the example then you will be asked for the value of INITS in this record. For reasons which will become plain when you use LETTERS, enter your own initials separated by full stops. Your entry will now be displayed next to the field name. If you made a mistake don't worry, you will be given an opportunity to put it right when you have entered all the data for this record. Continue to enter your details as prompted. If you just press "ENTER" when asked for a value then that field will not be left empty. Clearly you will not have an account number and you will not have invoices outstanding yourself. Thus for these fields leave a blank. If you later sort the file by invoice date for instance then records with no invoice data will be put at the front of the file.

Having entered your own details you will be asked whether you wish to alter anything. If you enter "Y" then you will be prompted to enter a new value for each field in turn. If you just press "ENTER" when prompted then the value for that field will be left unchanged. When you are happy with the record content, press "ENTER" when asked if you want to alter anything and you will be asked whether you wish to enter any more records. If you enter "Y" then the process above will begin again. If you just press "ENTER" then you will be returned to the main menu.

When you enter dates I suggest that you use the American format: YY/MM/DD rather than the British format: DD/MM/YY. If you do this then you will be able to sort your records by date using the sort routine in Datafile. You might wish to sort clients into Date of Birth order for example.

SORTING FILES

Select option "3" from that main menu. Assuming that you have more than one record on your file you can now sort them alphabetically or numerically.

The sort routine will first ask you for the name of the files by which you want to sort your records. For example, if you want to sort your file so that the records appear in alphabetical order of names then you might enter NAME.

If the field name that you have entered was a valid one then the message "SORTING" will appear on your screen. When sorting is complete you will be returned to the main menu. If you have entered the name of a field which does not exist then you will be asked to enter another. If you have forgotten the names you assigned to the fields of your record don't panic. Just press "ENTER" and you will be returned to the main menu. You can now select option "8" which will tell you the names that you gave (see print file detail).

AMENDING/DELETING RECORDS

Select option "4" from the menu. You will be asked for the name of a field. Say you know that the record which you wish to amend is that of Mr West. This means that the name WEST will be in the NAME field of that record. You should thus enter NAME when asked for a field and WEST when asked for a value for that field.

If you enter a field name which you have not defined then you will be asked to try another. Just pressing "ENTER" at this point will return you to the menu. If the value of the field does not exist on the file then a message will be displayed to this effect. For example, if you had not entered a record for Mr West when entering data.

Once the record that you require has been found you will be given the opportunity to alter each field in turn. If you do not wish to amend a particular field then just press "ENTER" when prompted for a new value.

To delete a record select option "5" from the menu. As when amending records, you will be asked for the information that the program requires to find the record that you wish to delete. When the record has been found it will be removed from the file and you will be returned to the main menu.

SAVING AND LOADING

Once you have got some data on your file you may want to save the file to tape. To do this select option "6" from the menu. The file will now be saved under the name by which it was defined above. If you followed the example your file will be saved as "CLIENT" DATA A$ ( ).

When the file has been saved you will be prompted to rewind the tape and prepare for verification. You will be returned to the main menu when verification is completed. If verification fails, use "GO TO 1" to return to the menu and then try again.

If you wish to update files which you have already saved to tape then select option "7" from the menu. You will be asked for the name of the file. If you have forgotten it then just press "ENTER". The program will then load the first file that it comes to on tape.

When the program has loaded your file it will decode the first record to determine the format of your file and the names which you gave to its field. It will then return to the menu. You can find out the names of the fields etc by selecting option "8".

PRINT FILE DETAIL

Select option "8" from the menu. The program will then print the names of each of the fields in the file and tell you the position that they occupy in each record.

For example if field INITS starts at 1 and ends at 6 then this tells you that INITS occupies the first 6 characters of each record, ie for record 2 inits would be A$, (2,1 TO 6).

To print the whole file select option "9" from the menu. Each record

on the file will be displayed in turn.

WARNING!

If you BREAK out of the program for any reason use "GO TO 1" to return to the menu. Do not use "RUN" since this will result in the loss of any data held on the current file.

A list if the variables used by Datafile is given in REM statements at the start of the program. You *must not* use these variables in your own programs when you use Toolkit to manipulate data held on files created by Datafile.

USING TOOLKIT

Each of the routines in TOOLKIT is designed to make using Datafile files in your program easy. Each routine is fully documented in REM statements.

1. Get field value. Each record in a Datafile file is stored as an element of the array A$. For example, the first record in the file will be A$(2). You will remember from the field definition stage that each field within a record also has a number and a name. The field number enables Toolkit to find out the position of a field in each record. It might, for instance, be A$(2,1 TO 6) as for INITS in the example. This routine when supplied with a record number in RN and a field number in FN will fetch the value of that field in record number RN. The value is returned in Q$ and trailing spaces are automatically removed.
2. Decoding dates. I have already explained the usefulness of storing dates in the American format. This routine will translate a date supplied in Q$ from the American form to the British form.
3. Removing spaces. If you have given a field in a record a value with less characters than the field length then the field will contain spaces after your value. This routine removes the unwanted spaces from a field value supplied in Q$ and returns the trimmed value in Q$.
4. Read header. I explained above that the first record on a Datafile contains information required by Toolkit to use the data in your file. When you use the LOAD routine this routine is automatically called to find out the format of your file.
5. Loading files. This routine will load a Datafile and call the header reading routine. The name of the file should be in Q$ on entry to the routine. If you don't know the name then let Q$ = "".
6. Find field number. The name of the field required should be in Q$ on entry to the routine. The routine will then find out the number of that field and return the result in FN. The value of FN allows you to get the start and end positions of that field from the numeric array F( ) which will have been filled by the header read routine. F (FN,1) holds the start position and F(FN,2) the end position. Thus, field 1 of record 1 extends from A$(1,F(1,1) to A$(1,F(1,2)).
7. Finding a record number. This routine returns in RN the number of the record which has a value equal to that of Q$ in the field designated by FN. You should define Q$ and FN before entry to the routine. The record number is returned by the routine in RN.

LETTERS: A SAMPLE APPLICATION

If you followed the example that I have given you will now have a file called CLIENT. LETTERS will input this file from tape and then write a letter to each client reminding them of the account that they have outstanding. Now you know why your own details should be entered first!

The listing of LETTERS should help you to develop your own applications. I hope that Datafile meets all your requirements.

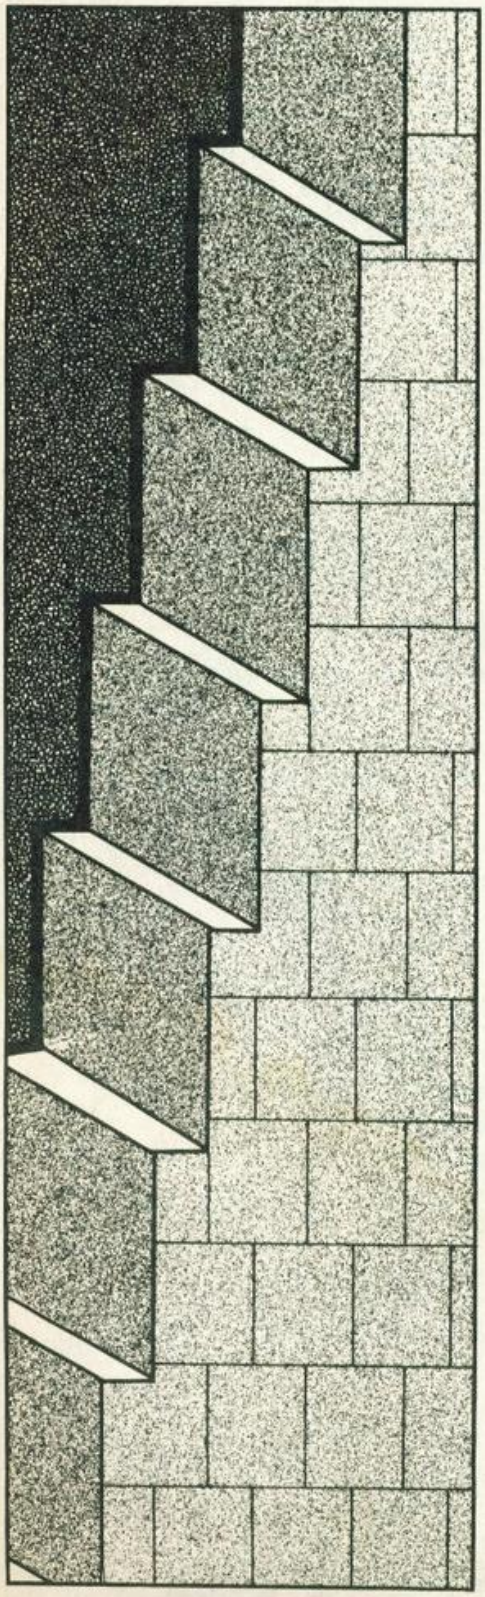
RAY ELDER

One Step Beyond

Programs may work perfectly well but still need a touch of expert development. Some ideas to get you thinking.



So you've done the really hard work, thought of something to write, sat down and produced a working, debugged program. You are pleased. The rest of the family make approving sounds and you decide that you will send your brainchild to be published. Some weeks later an envelope drops through the door and you rush to open it to find out just how many of those blue notes they are offering.

Shock! Horror! They are so unaware of real talent that they have rejected your masterpiece. Obviously they're pretty stupid so you cancel your subscription and look for another, more appreciative magazine.

Probably 75% or more of the programs submitted to magazines are rejected because they already have a similar program awaiting publication. The new one may have different features or been programmed differently, but once an editor has accepted a program then sooner or later we will publish it.

Most of the other rejections are because the program has been left in an unrefined state. What do I mean by that?

Steven Bridge has very generously given me permission to use his program to try and demonstrate how you can refine a program. I do appreciate how difficult it is to accept critism and to allow your work to be criticised in print must be twice as bad, so my most heartfelt thanks to him for taking the hot seat!

STEVE'S PROGRAM

Take a look at Program 1. This is Steve's original program, it has no drastic bug, (there is one minor one that is not fatal — can you spot it?), and it works fine, performing the task intended.

So what's wrong with it? Answer, nothing! But let's take what I call "the next step".

The first thing I noticed was the system of producing the superb music, obviously Steve had developed this note in the Data statement and used a system where 999 was the "rogue value" which signalled the end of that section.

However, now that the music was completely developed it is no longer essential. Also it seems a shame to only use it once. With this in mind I created a subroutine at 8000-8020 in my program (program 2).

The RESTORE allows me to call it more than once and find the correct starting point of the Data each time, knowing the exact length allowed a FOR/NEXT loop to be used, variables a and b can both be READ in one go and the whole lot fits in one line.

The next thing I noticed was the frequent use of PAUSE 100: CLS and so I thought another subroutine would be in order. On my listing I created this subroutine at line 8100.

PAUSING

Notice I used an empty loop instead of PAUSE. This is partly a leftover technique from my ZX81 days when PAUSE caused a screen flicker and an occasional crash. However I still use it on the Spectrum because on occasions a player may be slow to remove his finger from a key and cause the pause to be ignored. Remember that a pause is cut short by a key being pressed! Variable qu is initialised in Steve's program but never used. He was probably going to use it as a question counter then developed his program in another way. As it is redundant we ought to remove it for neatness' sake.

Steve owns a 16K Spectrum, so, for the sake of memory saving, I reduced variable "score" to "sc". It would have been better to have used "s" but I wanted to keep a balance between economy and legibility. For the latter Steve's name is the ideal!

THE BIG STEP

So much for the simple, nit picking modifications. To get a good overall view of his program, and in fact any program, it is essential to get a print out of the listing.

With a listing available the pattern of the program emerged and I traced it through looking for repetitive actions, initially in order to create subroutines but soon I became aware that it could be summarised in a simple form as follows:

1 Print at the same position the question number.
2 Print at the same position the question and 3 options.
3 Get an input.
4 Beep.
5 Check answer, if wrong print this at the same position and give correct answer.
6 Check answer, if correct print this, add 10 to score.
7 Next question.

The only things that changed were the questions, the options and the position the correct answer was in.

As so much was repeated I looked for a way to set up a format and use Data for the different questions each time.

The obvious one was the one I used. Each question was set up as a DATA line starting from line 9000, and each line consists of:

The question — a string variable
The 3 options — numeric variables
The position of the answer in the options — a numeric variable

This makes it simplicity itself to amend, alter, increase or replace any of the questions as they all follow the same layout. To store the three options I used a DIMensioned array. This would prove easier to find when printing the correct answer. Also while I was about it I thought it might be nice to give the correct answer even if the player had chosen correctly, a confirmation of his choice.

Finally I used variable a (for answer) to hold the position in the options of the correct answer.

THE FINAL STEP

Line 150 RESTOREd the Data pointer to the start of the questions and line 200 set up a loop counter i.

I decided that as we knew how many questions were to be asked a main loop was suitable.

Using the value of "i" it was straightforward to print up the question number as Steve had in his original. The data was READ into q$, each element of c() and "a" then the pause, cls subroutine was called. All in the one line.

Line 210 prints out all the information. Notice the loop "j" to print each c() element, and how I utilised its value to provide suitable spacing and the numbering. This was found by trial and error. Quite often a fair bit of time needs to be spent on just formatting the screen to give a balanced, effective display. Of course, each person has his own preferences for the way a screen is laid out, this only happens to be mine.

Line 212 gets the input. Here I used INKEY$. My reason was that the less key-pressing the user did the more he could concentrate on the questions. The fact that only a single number from one to three was required made it most appropriate. I also introduced a simple but effective check that a suitable key was pressed, all other keys (except BREAK of course) are ignored.

Line 215 provides the BEEP then goes on to check for the correct answer by comparing the VALue of the input a$ to variable "a" read from the Data. The variable "a" is also used to identify the correct element of c() for printing in both "correct" and "wrong" messages.

The line then increases the score and jumps over line 216 to line 220. Line 216 is the "wrong" message and is only reached if VAL a$ is not equal to "a" when checked by line 215.

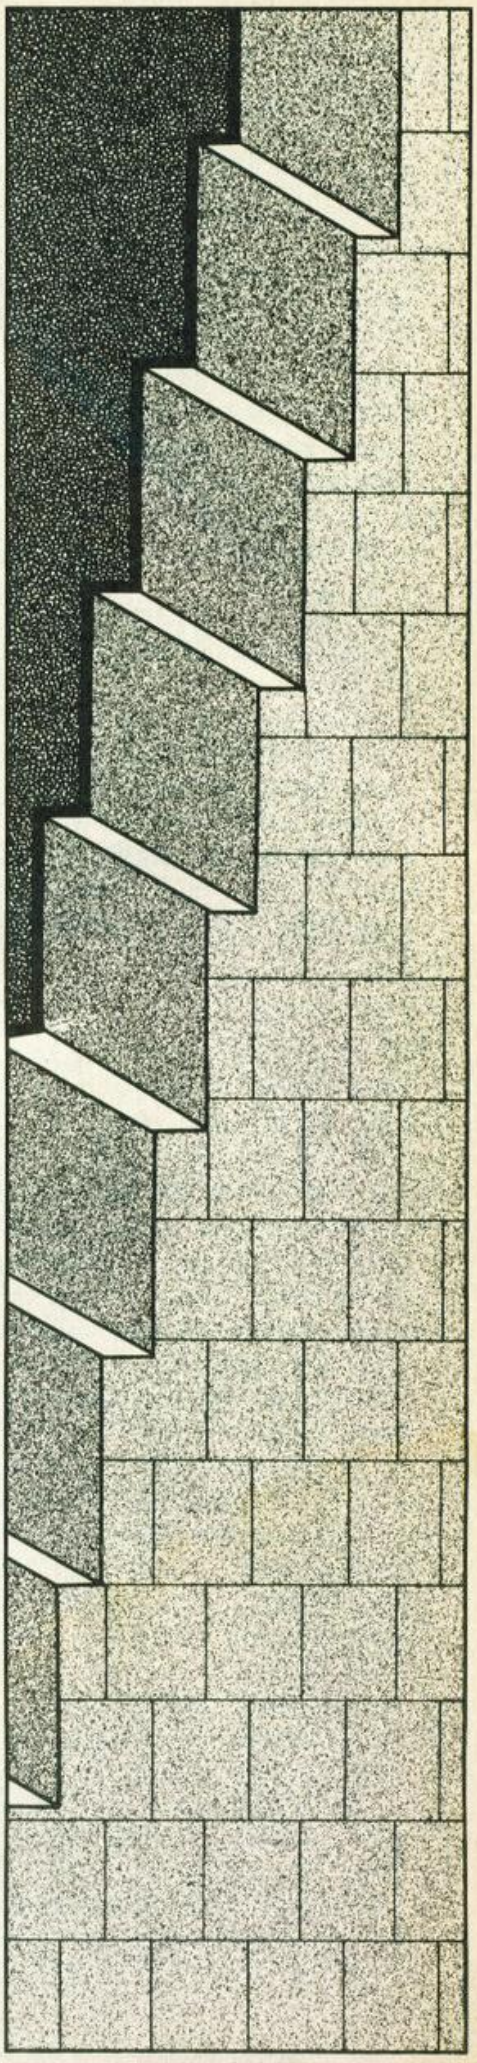
Lines 600 to 701 uses PAUSE 0 to wait for key. At this stage there has been a lengthy gap since the last required key press so there should not be much chance of lingering fingers.

FURTHER THOUGHTS

Well, Steve agreed with me that this program was much more efficient and easily adaptable than before, and we talked about other modifications it was now possible to make with the extra memory available.

Most of these we'll leave for you to experiment with. The first one was that, for the sake of user friendliness, a prompt to "Press 1,2 or 3" would be nice after each question the prompt removed on a valid input.

Then we thought that we could increase the number of questions. A possible idea — especially with a 48K machine — would have to be twice the number of questions in memory as were required to be asked and chose them at random. This would make for tremendous variation each time the game was played.



A system of checking that a question wasn't repeated would need devising for this!

We even mused on a way to present the options in a differnt order so that the data had to be remembered and not the position in the options. For this one we created these lines:

```
205 FORj=1 TO 4
206 LETx=INT (RND*3)+1:
LET y=INT (RND*3)+1: IF x=y
THEN GO TO 206
207 IFx=a THEN LET a=y: GO TO
209
208 IF y=a THEN LET a=x
209 LET z=c(x): LET
c(x)=c(y): LEY=c(y)=Z: NEXTj
```

This swaps two elements of c() at random, four times. Lines 207/208 keep track of the position of the correct answer.

Another idea was that the option data could be made into strings so that some answers could be words as well as numbers and open up a whole new range of questions. All that would be necessary would be to DIMension c$(3,4) and use c$() instead of c(), the number 4 would be altered to the length of the longest word in the answer.

As it was now getting to 1.30am and I had to write this lot up, we parted.

And so, here endeth the lesson.....

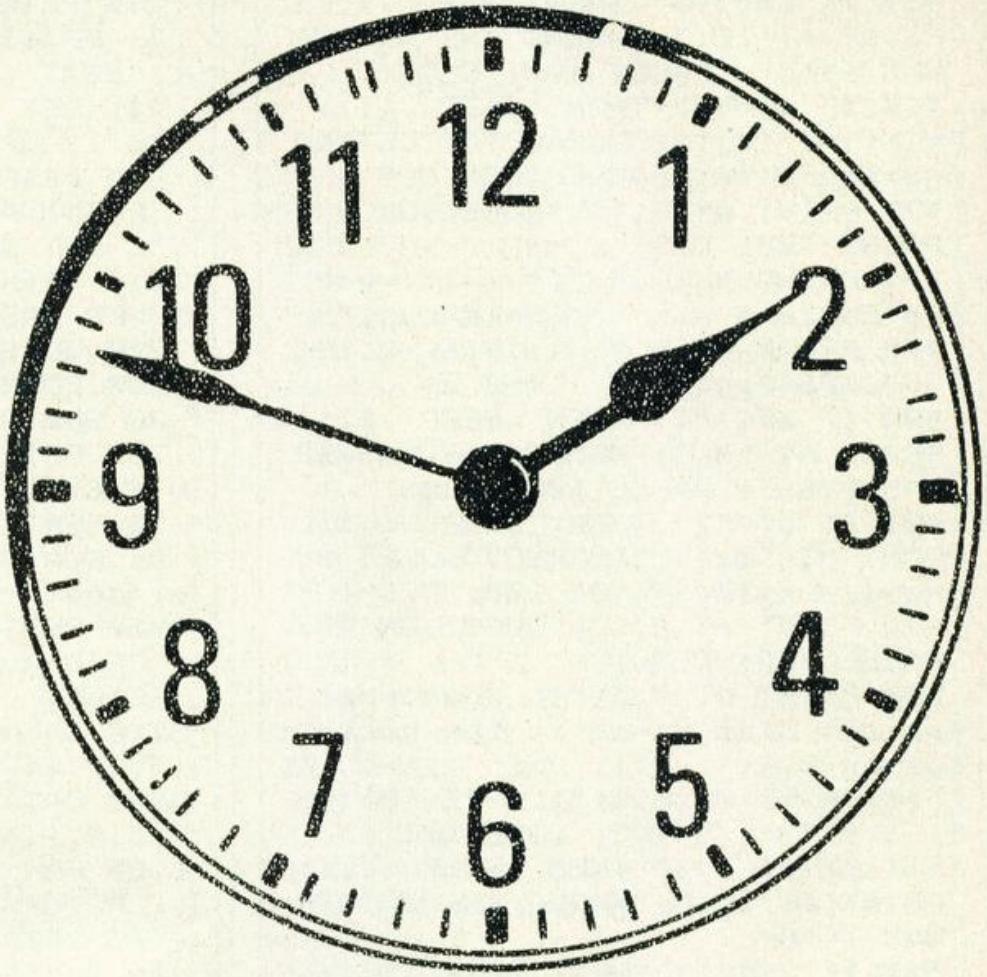
DOUGLAS RICHARDSON

Time Out

It may not fit on your wrist, but here's an easy way to turn your Spectrum into a wristwatch.

Chapter 18 of the Spectrum manual describes two analogue clock programs: the first version uses PAUSE as the 'hairspring' but, as the manual says, there is a difference of 1/50 between consecutive PAUSE numbers equivalent to half an hour per day. By altering the PAUSE valve you could probably increase the accuracy.



DIGITAL

This program prints out a digital watch and, as the result is displayed as a number, setting and synchronising are much easier — the PAUSE is compounded to give this accuracy. The performance of the watch then is dependent more on the stability of the timing delay function on the computer, rather then the ultimate accuracy of the internal clock.

The PAUSE at line 110 is the main reference, it allows a slight gain which is essential if a following PAUSE is to be corrective.

CALIBRATION

With PAUSE 49 at line 110 and REMs at 135 and 153, (see setting) run the watch for one hour. Seconds gained per hour times 5/6 rounded to the nearest integer gives you the PAUSE to be entered at line 135 in place of the REM. You must round down if you intend to use a third PAUSE for maximum accuracy. In the author's first check the gain was five seconds per hour:

5X5/6 = 4.16667

PAUSE 4 was then used at line 135.

If you opt for maximum precision then with PAUSEs entered at lines 110 and 135, and a REM at line 153, run the clock over a much greater length of time. Seconds gained per hour x50 will give you the PAUSE value to be entered.

Looking back to the author's example, the third PAUSE was not necessary as the error was only two minutes per day with one PAUSE, and 4.8 seconds per day with two PAUSEs. However, your Spectrum may be different and require this fine tuning.

Subject to stability, the target accuracy should be 24/50 seconds per 24 hours. This would give you an error of one minute per 500 days!

SETTING

For ease of setting, the seconds increment by five, but run normally once set. Set the time with the seconds just ahead of real time then press G when the time is correct. Note: line 730 Graphics is "1". Data is for effect only and may be changed at line 400.

BASIC Break

An easy way of disabling the Break key from within a BASIC program.

ON-ERROR processing is one of the few useful features omitted on the Sinclair machines but I realised quite recently that it would be possible (with the aid of a small machine code routine) to provide such a function. In the section of the Spectrum manual which contains details of the system variables (Chapter 25) there is a WORD entry called ERR SP at address 23613 which is described as the "Address of item on machine stack to be used as error return", which I examined by using the PEEK command in a function as shown below.

NO NONSENSE IN BASIC

It was obvious that the word at 23613 pointed at an entry in the machine stack and this was printed giving the value 4867 which is within the Sinclair ROM. I wrote a small machine code routine (not included here) which simply jumped to 4867 after placing a required value into the system variable ERR NR and found that I got the appropriate error report as shown in the Sinclair manual in appedix B. It seemed reasonable to assume that, if the stack entry pointed to by ERR SP was altered to address a machine code routine other than 4867, then any subsequent error would cause the alternative routine to execute.

I developed the machine code routine shown quite quickly and it worked for all errors except 12 (C in the Sinclair manual) "Nonsense in BASIC" which, despite considerable further effort, I could not trap without putting the machine into a recursive loop. The machine code routine consists of two parts, the first labelled START is run from BASIC with an appropriate USR nnnn call and this places the address of the second part, TRAP, into the machine stack entry pointed to by ERR SP. The TRAP routine is then entered on any "error" completion (from 0 upwards).

NAMES AND ADDRESSES

Although comprehensive comments have been included with the machine code, a little additional explanation is probably worthwhile, particularly since the routines were written to be run wherever they are placed in memory. First, the address of TRAP placed onto the machine stack must be the correct 'absolute address' regardless of where the routine is stored. This is calculated dynamically by the first two instructions, relying on the fact that the BC register pair contains the address of START on entry from the USR nnnn function. This absolute address is placed into the machine stack entry pointed to by ERR SP by the next five instructions. Secondly, the TRAP routine must be able to replace its own entry address onto the machine stack if it is to handle successive errors and although this is done by the two instructions starting at PUSH, the value used for TRAP in the LD DE, TRAP instruction must be modified in order to allow it to function correctly when loaded at differing memory addresses. The last five instructions in the START routine before RET place the corrected value into the instruction labelled PUSH to overcome this problem.

It must be stressed that instruction modification of this type is very bad programming practice and should only be used where there is no alternative. The modified intructions should be adequately explained as should those which carry out the modification. In this instance I could see no way of avoiding dynamic instruction modification but if anyone can offer an alternative approach I should be most interested to hear from them.

BASICALLY SPEAKING

When the trap routine is entered (on any BASIC completion) it first checks the given error code and passes control to the normal error handling code at 4867 if the error is either 0 (OK), 9 (STOP), or 12 (Nonsense in BASIC); this gives the BASIC programmer the option to allow his program to end normally when required by executing STOP or issuing a GOTO for a line past the end of the program. Without this way out the only way to terminate a program with TRAP incorporated would be to pull out the power lead, a point which will not be missed by anyone who wishes to "protect" the code of a BASIC program. As indicated at the beginning of the article error 12 seems impossible to recover from and is therefore also given back to the Spectrum routine to handle.

ROUTING DECISIONS

For any error other than 0,9 and 12 the TRAP stack entry is restored and then the number of the BASIC line chosen to begin ON-ERROR processing is placed into the system variable NWPPC. I chose line 9900, statement 1 but this could easily be changed as required by following the comments against the EQUates for GTOLL, GTOHL and GTOST. In order than the users' error handling routine (beginning at line 9900) can make routing decisions based on the line where the error occurred, the next few instructions save the line, statement and error numbers. These details could be placed into any spare memory locations (four bytes are required) but, since I do not have a printer, I often use the printer buffer as workspace and the routine stores the crash details there. The error line number is placed into the word at 23296, the statement number within that line is put into the byte at 23298 and the actual error number (increased by 1) is stored in the byte at 23299. It should be noted that the error is stored as a binary number, not in the equivalent character form given in the normal error reports expected from the BASIC; thus 21 would be shown following an attempted "BREAK" if the contents of 23299 was PEEKed.

Finally in the TRAP routine, the ERR NR is reset to 255 (its normal value) and a jump is made to the normal processing loop used when executing a BASIC program. The address (7030) of MAINL was found by a small routine (not included here) which printed the contents of the first few machine stack entries, which always shows 7030 immediately below the word with 4867. Although the routine could be used from a direct command it would serve little purpose since the trap address would be rest by the Spectrum routine when the command execution completed. The TRAP only needs to be set up once in a BASIC program and will continue to pass errors to line 9900 until an error 0.9 or 12 is encountered.

USES

Any BASIC programmer who has ever wished fo an ON-ERROR func-

tion will have few problems finding uses for this routine but, as a starter, it is fun to produce a small program which keeps going regardless of attempts to "BREAK" it and only finishes when it has done its job:

```
10    RANDOMISE USR nnnn
20    PRINT "STOP ME IF
      YOU CAN."
30    FOR a=1 TO 10000
40    PRINT AT 1,0;a
50    NEXT a
60    STOP
9900  PRINT AT 4,0;"NO, I
      WON'T."
9910  PAUSE 100
9920  CLS
9930  GOTO 40
```

Of course the value used for "nnnn" will depend on where you decide to place the TRAP routine. I have not included a loader with the routine details because so many good examples have been printed in the past that most people must be able to enter a machine code program without problems.

The function for displaying WORD length data from any memory location which was mentioned at the beginning of the article is:

```
10 DEF FN a(x)=PEEK x+256*PEEK
   (x+1)
```

whereupon PRINT FN a(23613) gives a value just below RAMTOP, and entering PRINT FN a(FN a(23613) should return 4867.

```
211400    START   LD      HL,OFFSET   ;get offset to trap from entry point

```

PAUL BATES

Game for a graph

Impress your teachers with a simple display of any sort of data.

This program will plot graphs from given information in one of several styles and can be reused without reentering the data in each of the plotting modes. It is Menu driven and simplicity itself to use. It can be used to display results from any type of data gathering exercise.

The program itself occupies about 5K and is entirely in BASIC. The Menu has six options:

1) Enter data
2) Choose dot character
3) Choose plot type
4) Draw graph
5) Regression analysis
6) Quit program

OPTIONS

OPTION 1 On selecting this option you will first be asked to enter the number of data pairs. The data pairs are then entered with the screen display the data pair to be entered next. After data entry you will be asked to give:

1) A graph title
2) An X axis title
3) A Y axis title

(Maximum 10 characters)

You will then be asked for a data to define the axes (this could have been done automatically using a bubble sort of data, but I prefer to define my own values to give a neat result). Enter X min, X max, Y min, Y max, as prompted. The screen will then be cleared and you will be asked to define the X and Y tic mark intervals.
For example:
X data ranges from
1 to 7.6
Y data ranges from
0 to 0.5

Xmin = 0 Xmax = 8
X tic mark = 2
Y min = 0 Ymax = 0.5
Y tic mark = 0.1

Beware of setting too small a value for tic mark interval, eg 0.5 for X axis — this would leave the X axis looking rather crowded. After data entry you will be offered a print out of the data pairs entered .

OPTION 2 Gives the choice of.*or+to portray the data points on the graph (see print out).

OPTION 3 Gives you the choice of a point only plot or having the points joined by straight lines (see print out).

OPTION 4 Draws the graph and can be used as many times as necessary after entering data (eg to change options 2 or 3).
(NOTE If options 2 and 3 are not set the default values give a point only print out, using a full stop to denote data position).

You will now be asked if you want a copy after which you will return to the Menu.

OPTION 5 Produces a table giving linear regression equation. This gives the equation of a straight line which best fits the data points entered. (This works over all the data points entered). The regression coefficient r indicates the goodness of fit.

r = 0 data does not follow a linear relationship
r = 1 perfectly fits equation determined

r values above 0.7 can be said to be a good indication of linear behaviour.

OPTION 6 Escapes from program giving a STOP report.

HOW IT RUNS

20-140	*Sets up Menu*
1000-1600	*Enter data option*
2000-2140	*Character option*
3000-3080	*Plot option*
4000-4040	*Draws axes*
4040-4320	*Plots tic marks and numbers axes*
4330-4420	*Plots Y axis title vertically*
4420-4520	*Plots points*
4700-4760	*Routine to join points by straight lines*
4800-4830	*Asks if copy wanted*
5000-5300	*Linear regression*

VARIABLES USED

A	*Menu option*
B	*Number of data points*
C	*X min*
D	*X max*
E	*Y min*
F	*Y max*
G	*Dot character value*
H	*Plot choice*
O	*Y values for plotting*
P	*X values for plotting*
Y	*X tic mark interval*
Z	*Y tic mark interval*
A$	*Graph title*
B$	*X axis title*
C$	*Y axis label*
D$	*Copy of data?*
E$	*Copy of graph?*
X(I)	*X value* }
Y(I)	*Y value* } *Data pair*

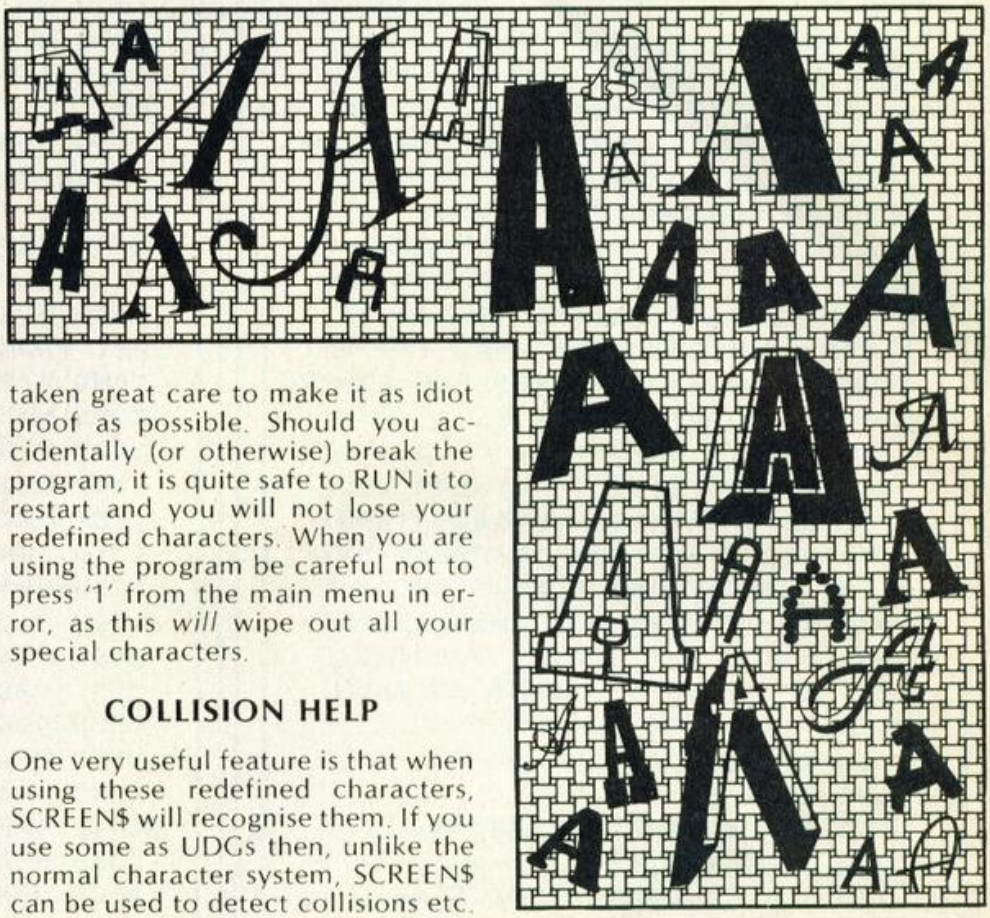
All Change

No it's not time to swop your Spectrum for something else. Merely a change of characters.

There are many occasions when an alternative set of characters is a very useful option — professional titles and Gothic style lettering for home programmed adventure games to name but two!

This program will allow you to redefine the entire character set and User Defined Graphics and to look at any RAM or ROM character at eight times the normal size. A simple machine code routine is used from within the program to copy the ROM character set into RAM. Notice that the program takes into account the memory size and makes appropriate RAMTOP changes with the CLEAR command.



TAKING CARE

Paul has made use of REM statements to explain the various sections of the program, you may leave these out of course, especially if working with 16K, but they are valuable when trying to debug any typing errors.

This is a good example of careful programming (although no doubt someone will find a way to crash it if they try) and Paul has taken great care to make it as idiot proof as possible. Should you accidentally (or otherwise) break the program, it is quite safe to RUN it to restart and you will not lose your redefined characters. When you are using the program be careful not to press '1' from the main menu in error, as this *will* wipe out all your special characters.

COLLISION HELP

One very useful feature is that when using these redefined characters, SCREEN$ will recognise them. If you use some as UDGs then, unlike the normal character system, SCREEN$ can be used to detect collisions etc.

VARIABLES USED

r,q	*Start of RAM character set.*
i$	*INKEY$ check.*
q$	*Titles.*
a$	*INPUT check.*
x,y,z	*Used in enlarging characters.*
a	*Value of input, etc.*
w,c	*Data for drawing/inputing characters.*
f,b,g	*FOR-NEXT variables.*

Thinchars

Put the squeeze on your screen with this slimmer character utility.

Thinchars is a machine code routine written for the Spectrum which displays 42 characters on each line of the screen, instead of the usual 32. Each character is 6 pixels wide instead of 8, including a blank column between letters. The shapes of the 96 characters (codes 32 to 127) are stored in a table at the end of the routine. Each character takes 5 bytes, one per column, which are read from left to right; the sixth column is always blank and is not stored in the table. The routine is *relocatable*, which means that it can be loaded at any address in memory and will work without modification. This makes use of the fact that when a "USR n" statement is executed in BASIC. the bc register is loaded with n, the start address of the routine called.

VARIABLES

Thinchars takes the text to be printed from the 1-dimensional character array s$, which must be set up by a DIM s$(. . .) statement at the start of the program to ensure that it is the first variable in the variables area. (An ordinary string variable would be moved to the end of the variables area each time its value was altered.) If the first variable is not array s$, the routine returns without doing any printing. The first two characters of s$ are not printed, but their codes are used as the x and y co-ordinates of where the printing is to begin; the x coordinate is the same as that used for PLOTting, but the value runs from 0 for the top row of the screen to 184 for the bottom row (to allow printing on all 24 rows), and is rounded off if necessary to a multiple of 8. The end of the string to be printed is signaled by a character with code 128. So a general statement to set up the string would be LET s$=CHR$ x+CHR$ y+ "text"+CHR$ 128. There is no limit to the length of s$; if the printing reaches the foot of the screen, it continues at the top.

COLOUR

Any of the colour items (PAPER, INK, INVERSE, OVER, etc) can be set before THINCHARS is called. Two ROM routines are used: call 3405 copies the permanent screen attributes to the temporary ones; and call 3035 uses the screen address in the hi register to set the attributes in the appropriate square. (This is done at the left hand and right-hand edges of each character, as they may be in different attribute squares.) The routine will fill the screen with 1008 characters in about 1.4 seconds.

LOADING THE ROUTINE

The routine is 199 bytes long, followed by a character table of 480 bytes; suitable start addresses at 64600 for a 48K Spectrum and 31900 for a 16K Spectrum, but any address may be used, and when the routine has been saved (SAVE "thinchars" CODE 64600,679) it may be reloaded to a different address. Remember to enter CLEARN n, where n is less than the chosen start address, before loading the routine. The following BASIC program may be used for loading: (addresses are in decimal, bytes in hex; enter x to go back one byte, s to stop).

LOADING PROGRAM

```
10  DEF FN h (p$)=CODE p$ — 48 —
    7*(p$>"9")-32*(p$="a")
20  DIM a$ (2)
30  INPUT "Start address:";a
40  INPUT (a), LINE a$
50  IF a$(1)="s" THEN STOP
60  IF a$(1)="x" THEN LET a=a-1: GO TO 40
70  POKE a, 16*FN h(a$(1))+FN h(a$(2))
80  PRINT a; TAB 6; a$
90  LET a=a+1: GO TO 40
```

LOADING THE CHARACTER TABLE

Figure 1 shows the 480 bytes of the character table, and the characters which they represent. They are loaded into memory immediately following the routine. Alternatively, the characters may be generated by means of the program THIN.GEN. In this, you are given a 5×8 grid in which to create a character, which is then stored in the appropriate place; the program displays all the characters so far loaded, and any of them may be returned to the grid for modification.

HOW IT RUNS

10	Ensures that s$ is the first variable
130-160	Obtains start address of THINCHARS; checks first character and halts if it is incorrect
200-260	Sets up a copy of the character set in s$; the BEEP in line 250 is to convince the user that something is happening
270-290	Print box for character, character set and instructions
300	Set cursor to top left-hand corner
310	Print cursor
320-330	Wait for key; remove cursor
340	Plot or unplot a square in the grid
370-390	Move cursor
400-496	Load grid with character i$. Line 460 tests if the bit read from the character table is the same colour as the relevant square on the grid, and if not, changes it. POINT was used instead of SCREEN$ as the latter treats both white and black squares as spaces.
500-595	Store grid in character table in place determined by i$, and re-print the character set
600-620	Prints the character set (on yellow PAPER, so that the user can see how many empty spaces are left).

MACHINE CODE LISTING

The addresses and the numbers in the assembler listing are in decimal, and the addresses are relative to the start of the program.

```
000 C5          push bc          save routine start address
001 DDE1        pop ix             in ix

ALAN RENWICK

Guitar Tutor

We can't promise a Top Ten hit, but we can demonstrate chords and help you tune up.

Written for the 48K Spectrum, this is a must for any guitarist, containing routines for expert and beginner alike, and is also a valuable educational aid. The program uses approximately 13.5K but 16K users could break the program into smaller units and record them as sequential programs.

CHORD CHECK

The program is designed to go one step beyond guitar tutor books by making use of the sound capabilities of the Spectrum to aid tuning and to check that you are playing chords correctly. There are limits to the ability of the Spectrum of course, one of which being the fact that only one note at a time can be played but Alan uses what is available to the full.

The program is structured in a simple manner which makes for easy expansion or contraction of the routines. Each particular subject is coded at a block of lines which is a multiple of 1000. This is selected from line 595.

If you renumbered lines 6000-6030 to 5960-5999 you would have room for three routines of your own at 6,7 and 8000. The possibilities are endless — how about lyrics, song structure and rhythm patterns?

CARE WITH DATA

The whole program is built around data statements and it is important that these are typed in accurately — especially lines 9210 to 9420. If the correct number of spaces are not left the program will crash. Note that the flat character is the UDG character A, but in the listing I replaced it by "b" because my printer would print it as "A" and Ab is clearer then AA!

Twenty chords are included but more can be added if you wish by increasing the 20 in line 9210 DIM. and adding the extra chords to the DATA statements. These are constructed as follows:

C$(x,1 to 12)	*Notes which appear under the chord window.*
13 to 16	*Print position for finger 1.*
17 to 32	*Print position for other four fingers.*
33 to 39	*Chord name.*
40 to 57	*Values of notes for BEEP if user wants to hear chord.*

ADRIAN MARSH

ROM roundup

A quick guided tour of the Spectrum ROM reveals some useful routines.

The Spectrum ROM holds many secrets. The most interesting are the monitor routines and in this article I shall outline a few of these routines, and explain how they may be used.

ON SCREEN PRINTING

There are a number of ways of transferring information to the screen:

1 Hex address: 0B24-0BDA. This is the PRINT-ANY character subroutine. On entry the HL register pair holds the pixel address of where the character is to be printed; the BC register pair holds the current line and column values and the A register holds the character code.

This method is complicated so it may be easier to use the second method.

2 This subroutine is contained within another, therefore the whole routine begins at 0D68 and ends at 0EAB. At the present the reader is interested in location 0DD9. This sets the printing locations to BC:

i) Load the BC register pair with the appropriate values.
ii) Call CL-SET and Call 0DD9 which enters required values.

BC is equivalent for a position AT a,b; the B register holds the line (hex) 18-a and the C register holds the column (hex) 21 -b. Therefore, a routine to produce an equivalent to PRINT At 11,15; would be:

```
01 13 0D      LD BC, 0D13
CD D9 0D      CALL 0DD9
3E??          LD A, (character)
D7            RST 0010
C9            RET
```

3 The routine PR-STRING can be used tp print any string. The monitor routine consists of:

```
PR-STRING address   203C
(label) PR-STRING   LD A,B,
                    OR C
                    DEC BC
                    RET Z
                    LD A,(DE)
                    INC DE
                    RST 00010
                    JR PR-STRING
```

Any string of characters can therefore be printed by:

i) Loading the start address into DE
ii) Loading the length of the address into BC
iii) Call the PR-STRING at address 203C

CLEARING THE SCREEN

The B register holds a value in the range of (hex) 01-18. Therefore, (hex) 18 would clear the whole screen.

The CL-LINE routine begins at 0E44 and is very short:

```
06 18         LD B, 18
CD 44 0E      CALL CL-LINE
C9            RET
```

This will clear the entire screen whereas if B were loaded with 17, all but the top line would be cleared.

SOUND

There are two routines in the ROM for producing sound, the BLEEPER and the BEEP.

1 The hex address for the BLEEPER is 03B5-03F7. On entry the HL register pair hold the pitch and the DE register pair holds the duration. The duration value has to be increased as the pitch value is decreased. The pitch for middle C is 0666 and the duration for a second is 0105 so a routine for BEEP 1,0 would be:

```
11 05 01      LD DE, 0105
21 66 06      LD HL, 0666
CD B5 03      CALL BLEEPER
C9            RET
```

2 The hex address for the BEEP routine is 03F8-046D. This routine uses the calculator to change the duration and pitch into appropriate values for the DE and HL register pairs.

USING THE KEYBOARD

The main routine is the KEY-SCAN.

1 Hex address for the KEY-SCAN is 028E-02BE. On leaving the routine, DE is returned with a key value. The zero flag is reset if more than one key is pressed at the same time. The D register indicates which shift keys are being pressed and the E register contains the key number (hex) 00-27.
2 At location 02BF-03B4 are found the KEYBOARD subroutines. These handle the repeat facility and decode the key-value to give the required character code. If the code is accepted then it is placed in the system variable LAST-K and bit 5 of the FLAGS is set.
3 At location 10A8-111C there is the KEYBOARD-INPUT routine. This routine copies the value from LAST-K and depends on bit 5 of the FLAGS. It then returns with the carry flag set or reset if the code is printable.
4 The subroutine at location 15D4-1651 literally has the effect of a PAUSE 0 or 'waiting for a key to be pressed'. So, a pause 0 in machine code would consist of:

CD D4 15 CALL 15D4

LOADING AND SAVING

The whole routine starts at 04C2 and ends at 09F3.

1 SAVING This subroutine begins at 04C2-053E and passes the DE bytes by starting at the (IX) location and continuing to the cassette recorder with the initial marker byte and parity byte. An example of this is:

i) The amount of bytes to save is 255 (FFh)
ii) The block is stored at location 25000 (61A8h)

Therefore:

```
3EFF          LD,A,255
DD21 A861     LD IX, + START
110 001       LD DE, + COUNT
C9            RET
```

This routine saves 255 bytes starting at 25000. However, these bytes are saved without a header, and can only be loaded if the count is known.

2 LOADING This subroutine begins at 0556-0604 and loads the DE bytes and the IX register pair points to the first location. When loading the carry flag must be set, but if it is reset then VERIFY can be

used. Therefore:

```
(37)                    (SCF loading only)

3EFF                    LD A,FF
0D21 A861               LD IX,START

110001                  LD DE,COUNT
CD5605                  LOAD ROUTINE
C9                      RET
```

This routine loads 255 bytes into 25000.

I shall now continue to shed some light on the RST commands or restart commands.

1 RST 0 (0000-0007h). This does a number of things in this order:

i) Disable the maskable interrupt
ii) Clears the A register
iii) Loads the DE register pair with 65535 (FF-FFh)
iv) Jumps forward to 11CB

At 11Cb are the initialisation routines (equivalent to NEW).

2 RST 8 (0008-000Fh).

These are the error routines. There are two outcomes of this:

i) The stack will be cleared.
ii) The appropriate report is given.

3 RST 10(0010-0012). This is the PRINT A character routine. A jump forward to location 15F2 is made.
4 RST 18 and RST 20 (0018-0024h). This fetches the current character pointed to by the CH-ADD routine.
5 RST 28 (0028-0029h). This jumps forward to location 335B which is the first address of the calculator.
6 RST 30 (0030-0037h). This is the BC-SPACES and jumps forward to 16 9E to make a space in the work space.

A useful routine at 11DA is the RAM-CHECK routine. All locations from RAMTOP to 4000 are tested. The HL register pair holds the address of the last location of memory available.

By now the reader should have a good idea of the monitor programs in the ROM. Although I have only outlines a handful, they are sure to come in useful in writing new machine code routines.

HUGH WALKER

Warlock

Adventurous types strap on your shields and swords (after typing this game in first, of course!).

One of the problems with adventures is that you can often complete the game from the knowledge gained by entering it. Hugh has adopted two methods to prevent this from spoiling your pleasure. Firstly he has not REMmed the listing and has laid it out in an illogical way, and secondly he has used random elements to provide surprises without losing too much player skill.

You are a 'novice-hero' whose task is to raid the Warlock's mansion and find all his gold, using the keys which you find to unlock any doors and fighting off his pet monsters with your sword and shield. Each key may be used once only, but not all the doors are locked.

TREASURE

The questionable ethics of a young hero turning thief are satisfied by the fact the Warlock's treasure has been extorted from the oppressed peasants in his locality. Should you be successful, you will, no doubt, restore the gold to its rightful owners. The hero-rating which you acquire directly reflects the amount of gold you have found, and no one, except the Warlock, can take this from you. Indeed, it is possible that, in some future program, you will return as a wiser, stronger hero to deal with the Warlock's permanently!)

To find the treasure and the keys you must open doors, explore hallways and defeat monsters whenever the opportunity arises. However, you may not find anything and be given an opportunity to rest and build up your strength. This strength is limited and it is reduced by fighting, so the opportunity to rest is useful. The Warlock is away at the start of the game, but he may return and catch you. If he does he will either fight you, proving difficult to chase away, or he will use his magic to turn you into a small creature, robbing you of your hero status (hero-rating).

TIME TO GO

When you have collected all the treasure you will be congratulated and told to find your way out "...if you can!" The way out is through a door on level 0 so you are also told which level you are on. You then have to make your way to level 0, open the door (which may be locked) and leave triumphantly.

Whenever you are confronted by a monster or the Warlock himself in a fighting mood, you will be given the option to "hit it (him)" or to "run away". You cannot kill the monsters (you are only a young hero) but you can chase them away. However, some are difficult to defeat and each blow you deliver uses up some of your strength. If you use up all your strength, then you have lost! Nevertheless, if you choose to run away you will be called a COWARD and lose some of your HQ (hero-quotient), and you MAY lose some treasure...or, you MAY be trapped by the monster. Your HQ is a factor in calculating your 'Hero-rating'...so your honour is at stake! If your attempt to hit the monster, or Warlock, fails to chase it away or your attempt to run away has been unsuccessful, you will be given the option to 'hit it' or 'run away' again.

As you move around the mansion you will find one of three locations: 'Door', 'Hallway' and 'Stairway'.

Oh! By the way, only the computer knows what the total amount of treasure to be found is and it won't tell you until you have reached that amount (it will be between 1500 and 2500 coins). Good luck!

INSTRUCTIONS

1. *Door: (may be locked) :you have two options: 'Open' or 'Leave'.*
   If you open the door, you may find a reward...or a monster...or nothing, and have to leave. If the door is locked and you have no key, then you have to leave...each time you leave a location, whether by choice or not, you risk meeting a monster, which may result in loss of treasure.
2. *Hallway : three options : 'Move', 'Explore', or 'Status'.*
   Move: moving backwards or sideways may result in a bump on the head from a low beam, causing some loss of strength; moving forwards is safe because you would see the low beam in front of you!
   Explore: you may find treasure, a key, a rest, a monster or another location or nothing and have to leave...with the same risk as above.
   Status: Lists your possessions, what level you are on and returns you to the options 'Move, Explore or Status' when you are ready.
3. *Stairway :three options: 'Up', 'Down' or 'Leave'.*
   You will not know if the stairway goes up or down until you try. If you make the wrong choice you will have to leave.

VARIABLES USED

1. The following are DIMensioned arrays, READ from DATA.

m$(9,9)	*:The name of each monster (and Warlock).*
a$(3,9)	*:The three locations found (door, hallway, stairway).*
k$(3,6)	*:The three small creatures into which the Warlock may turn you.*
m(9)	*:The resistance of each monster to your blows.*
n(9)	*:The endurance of each monster to withstand successful blows.*
g(9)	*:The value by which your Hero-quotient is increased when you beat each monster and the length of*

each monster's name (for tabulation in lines 3090 and 3110).

z(11) :The length of the BEEPs in line 4000.

y(11) :The pitch of the BEEPs in line 4000.

2. The following are 'single' variables.

hi :High Score, carried forward to successive games ('hi'='hr')

*hr :Hero-rating, ie overall score in each game.

hq :Hero-quotient, increased by defeating monsters (by a randomly-adjusted value of 'g').

ded :The number of monsters beaten.

ht :The force of your blow when you hit a monster (randomly selected).

blo :The value by which a successful blow reduces the monster's endurance.

mn :Random value (1 to 9) to select monster from m$ (array), and associated values of 'm', 'n', and 'g'.

str :Your strength, initally 500: reduced by fighting or bumping your head: increased by resting.

wl :The value by which 'str' is reduced when you bump your head (randomly selected).

tres :The maximum amount of treasure to find (between 1500 and 2500; randomly selected).

tr :A logic variable to change course of program when 'tres' has been reached. It prevents more treasure being found and allows you to leave from line 1630 if you are on level 0.

csh :The amount of treasure you possess.

cn :The amount of treasure found each time.

ky :The number of keys in your possession.

wy :Random value (1 to 3) to select a$ and direct GO SUB in line 140.

fl :The level (floor) which you are on.

bp :Used in lines 400 to 460; 'bp'=+1 'Up' and bp=−1 for 'Down': it alters 'fl' and the pitch of the BEEP routine (line 460).

(*Your hero-rating is calculated by adding 'csh'+('ky'*5) + 'hq' and is uprated each time you change your location). In the course of the program 'f', 'i' and 'h' are used as FOR-NEXT variables for various purposes.

Please note:

1. Unlabelled Random-values are used to direct some of the 'GO TOs'.
2. INKEY$ is used for your responses to the various options offered you. This allows single-key entries to speed up operation of the game. However, PAUSEs and BEEPs have to be used to slow down the display.

EXTRAS

1. A lateral dimension could be added to this program so that the 'Move' routine translates sideways, forwards or backwards; within a 2-dimensional array from a fixed exit point, maintaining the vertical dimension ('fl') requirements to qualify for successful exit at line 1630. This exit point could be randomly generated in each game and added to the exit requirements at line 1630.
2. A random value could be generated (say between 0 and 10) as the vertical dimension which 'fl' would have to equal to qualify for successful exit at line 1630.

HOW IT RUNS

Line 20 :Initialise High Score for successive games.

Lines 50 to 60 :*Initialise each game (routine completed by calling subroutine 5000 to 5500)*

Lines 100 to 150 :*'Core-routine' to which all other routines return. Selects and PRINTs locations and directs GO SUB for each.*

Location *(lines 200 to 460)*

Lines 200 to 220 :*'Hallway' PRINTs and acts on options, using 'Go TO': 500, 600, or 700.*

Lines 300 to 330 :*'Door' PRINTs and acts on options using 'GOTO': 800 or 8200.*

Lines 400 to 460 :*'Stairway' PRINTs and acts on options, routine complete.*

Response to 'Hallway routine *(lines 500 to 780)*

Lines 500 to 520 :*Move selected by INKEYs "1" in line 220; PRINT's etc options (complete).*

Line 600 :*'Explore' selected by INKEYs "2" in line 220; uses 'GO TO' line 1650.*

Line 700 to 780 :*'Status' selected by INKEYs "3" in line 220, PRINTs possession, score, what level you are on and returns to line 200 when you are ready.*

Response to 'Door' routine

Line 800 :*'Open' selected by INKEYs "1" in line 320. Random chance of: (GO TO 1500 door locked) or (GO TO 1600 door open).*

Responses to 'Explore' and 'Door opens' routines *(lines 1000 to 1460)*

Lines 1000 to 1800 (from 1650) (or 8200) :*'Meet Monster' routine; Selects monster, PRINTs and acts on options to fight (GO TO line line 3000) or run away (GO TO line 8500) or random chances of monster stealing gold instead of fighting and if Warlock is met, random chance of Warlock using magic (GO TO line 1700).*

Lines 1100 to 1150 :*'Find gold' routine, from line 1650 (also from line 3130). If maximum amount has not been found, calculates the amount of each find (amount reduces in proportion to total already found), PRINTs amount found and increments gold score, then checks gold score against maximum.*

Lines 1200 to 1220 :*'Find key' routine from line 1650 (also from line 3130). Random chance of finding a key, or another location. if a key is found, PRINTs and increments one key to key score.*

Line 1300 (from 1650) :*'Find nothing' routine; uses lines 8000 to 8210 to complete routine.*

Lines 1400 to 1460 (from 1650) :*'Find rest' routine; random chance of finding rest of another location. If rest, then PRINTs, BEEPs and increments strength score.*

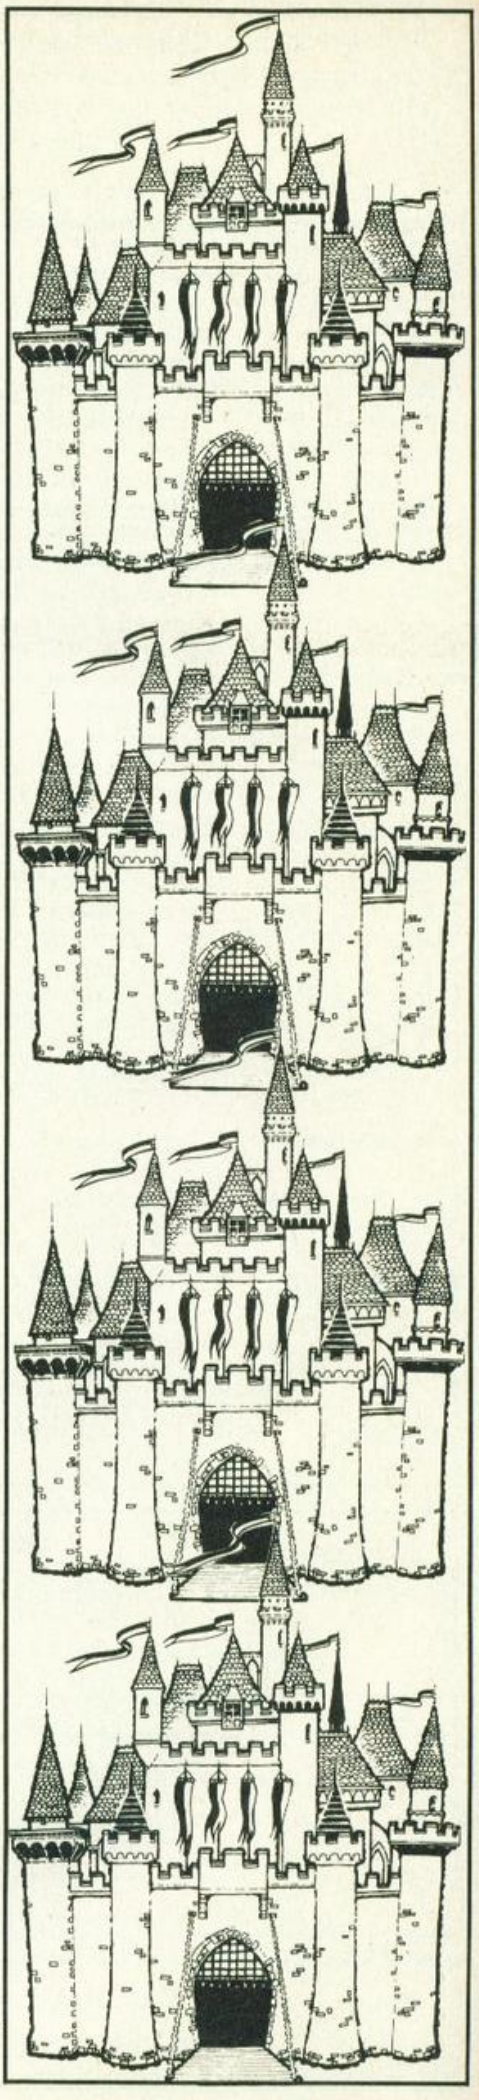
Continuation of 'Door' routine *(lines 1500 to 1650) from line 800*

Lines 1500 to 1550 :*'Door locked' routine; checks if you have a key (if not then GO TO 6500). If you have a key, then asks if you want to use it? (if "No" GO TO 6500). If "Yes" then decrements one from key-score and carries on to line 1600.*

Lines 1600 to 1650 :*'Door opens' routine; (from line 1550 or line 800). PRINTs, uses 4100 for BEEPs, checks if you have finished and randomly selects 'GO TO' :lines 1000, or 1100 or 1200 or 1300 or 1400.*

END routines *(Lines 1700 to 2050)*

Lines 1700 to 1770 :*'Bitter End' routine; (Warlock 'uses magic') from line 1030. PRINTs, selecting k$ from array, uses line*



1900 to 1950 to complete.

Lines 1800 to 1880	:'Successful End' routine; from line 1630. PRINTs scores and uses 1900 to 1950 to complete.
Lines 1900 to 1950	:'Hi score' and 'Play again' routines; from lines 1770, 1880 or 2050. Increments High Score and asks if you want to try again. If "Yes" then goes to line 50; if "No" then STOPs.
Lines 2000 to 2050	:'Out of Strength' routine; from line 3010. PRINTs and uses lines 1850 to 1950 to complete.
Lines 2500 to 2570	:'All treasure found' routine; from line 1140. PRINTs, sets logic variable tr to 1, returns to 'core-routine' (L 100).

Fight Routine (lines 3000 to 3130), from line 1080.'

Lines 3000 to 3040	:Calculates the force of your blow, decrements strength, checks to see if you injured the monster, if you did, then 'GO TO' line 3050, if you did not, then goes to line 1050 for another try.
Lines 3050 to 3130	:Calculates how badly you hurt the monster, decrements monster's endurance; if monster is still fit to fight, then returns to line 1050, if monster is not fit to continue then PRINTs, increments 'hero-quotient', uses 'GO TO': 1100 or 1200 for reward.
Line 3500	:'Title' subroutine: PRINTs title, used in various parts of program to which it returns.
Lines4000 to 4500	:Beep routines (subroutines). Returns to 'core-routine' if 'GO TO 4000' etc is used.
Lines 5000 to 5190	:'Initialise routine' subroutine called by line 60. DIMs arrays, READs arrays from DATA (lines 7500 to 7800), PRINTs instructions and initialises variables, uses line 5500 to continue.
Line 5500	:'CONTINUE' routine; from various parts of program, returns to 'Core-routine' (1200)
Lines 6000 to 6500	:'Monster steals gold' routine; from line 1040. PRINTs, decrements gold-score, PRINTs new gold-score, checks if new gold score is below maximum and resets tr if necessary.
Line 6500	:"No!" routine from lines 1510. 1540; uses GO TO 8000 to continue.
Line 8000	:'Leave routine' from lines: 320, 430, 1300, 1460 and 6500 — carries on to 8200.
Lines 8200 to 8210	:Random chance of meeting another monster. From lines 330, 420 and 8000.
Lines 8500 to 8530	:'Run away' routine; from lines 1070. PRINTs "Coward" and decrements 'hero-quotient' then random chance of:
Line 8520	:(a) Dropping gold uses GO TO 6010 to decrement gold-score and return to 'core-routine'.
Line 8540	:(b) being trapped; returns to line 1050 for another try.
Lines 9000 to 9050	:'SAVE' routine; accessed by 'BREAK', 'GO TO 9000'.

Zipping and Zapping

Spice up your games with a few novel sound effects. Zip 'em and zap 'em!

Anyone who has tried to write their own games on the Spectrum will have found the BEEP command very limited and many people have bought add-ons to raise the Spectrum's sound to that of the BBC micro in versatility as well as volume. However, for most people £20-£30 is a high price for such a simple task.

Fortunately, there is a compromise solution which uses software rather than hardware to achieve special effect sounds such as explosions at negligible cost.

ZIP!
by David Mold

This is a m/c program which produces a much more interesting sound from the Spectrum speaker than its usual 'beep'. It can be called very easily from BASIC and the sound produced can be varied by using DEF FN. The program was written for 16K Spectrum and could easily be run on a 48K model, although the addresses should really be changed to put it higher in memory on the 48K version.

The listing of the m/c is in three columns: the first shows the address of the corresponding bytes, the second shows the decimal codes of those bytes and the third shows the Z80 opcodes.

It should be entered to the address 32500 using the short BASIC program.

The code can then be SAVEd using:

SAVE "beep" CODE
32500,32

and when it is required for use with a program — existing or to be written, it can be loaded from tape thus:

CLEAR 32499:LOAD "beep" CODE

and then used in conjunction with the program as described previously.

To call this routine from a program, first

DEF FN b(x,y)=USR 32500

then, when the beep is required use

LET 1=FN b(N,N)

where N,N represents two numbers you can specify which, very broadly, set the duration and pitch respectively. They should both be between 0 and 255 inclusive. Experiment to find the effect of varying the two factors. Also, try

POKE 32528,12

as a direct command, and experiment further to find its effect.

BASIC PROGRAM

```

ZAP!
by E. French

The second program contains three pre-defined sounds:

1) A Zap
2) A Machine gun shot
3) An Explosion.

As it stands the program occupies ¼ KByte which is normally reserved for the printer so as to conserve memory.

The program is in six parts: the first contains two subroutines which can produce white noise (for gunshots and explosions) or tones (for sirens and zaps). The second, third and fourth parts produce the predefined sounds. The two remaining routines play the user-defined sound: the first with white noise (a

kind of rushing sound) and the other with tones.

USER DEFINED SOUNDS

The BEEP command produces a neat regular regular waveform reminiscent of an electric organ which is not very useful to the games programmer.

Special effect sounds are not so simple and require more information in order to be produced. With a BEEP command it is necessary to provide only two figures or parameters: the first indicates how long you want the sound to last for and the second indicates the pitch of the resultant sound. A special effect sound can best be thought of as a succession of BEEPs one after another. However, special effect sounds cannot be produced by the BASIC BEEP command because the interval between individual BEEPs is too great.

This, thankfully, is not an insurmountable problem, because by using machine code routines the delay between BEEPs becomes neglible.

If sounds such as explosions are to be produced, successive BEEPs will not suffice. Such sounds are produced with white noise which on its own gives a rushing noise.

Now to the practicalities: *There is no need for the user to know anything about machine code.* All that is required is to follow these instructions:

1. Type in listing one.
2. RUN it.
3. Type SAVE "Sounds" CODE 23926,256 and enter.
4. Rewind the tape and VERIFY""CODE and enter.
5. If you get the message "Tape loading error" then go to stage 3.
6. The BASIC program has now done its job and it is safe to NEW. To recover the machine code routine use: LOAD""CODE.

If you have an assembler you should type in listing 2, assemble it and SAVE the code.

RUN OLD RAY GUN

The next thing you will want to do is listen to your new sounds. To do this simply enter the following:

```
10  PAUSE 0: REM waits for
    keypress
20  LET (an unused variable)
    =USR 23375; REM make a
    ZAP
30  GO TO 10: REM do it again
```

When this is RUN it turns your Spectrum into a ray gun. By changing line 20 to:

```
20  LET (an unused variable)=
    USR 23386
```

Now your Spectrum is a machine gun. And making line 20 read:

```
20  LET (an unused variable)=
    USR 23398
```

Now whenever you press a key your Spectrum happily explodes!

So to sum up:

```
LET  (an unused variable)=USR
     23375 produces a Zap.
LET  (an unused variable)=USR
     23386 produces a machine
     gun shot.
LET  (an unused variable)=USR
     23398 produces an explo-
     sion!
```

YOUR OWN SOUNDS

The more skilfull will want more than just these three and impressive sounds can be custom made. However, take great care: if you go wrong on this section you might have to wait several days before your machine has finished your sound.

So, to produce your own effects you must tell the computer the length and pitch of the eight beeps which make up the sound you want to produce. You must also tell it how many times to play each beep. Thus, for each beep there are three parameters: length, pitch and the number of times you want each beep to be produced. So in total there are 24 parameters. The procedure to tell these to the computer is:

```
10  DATA (length of 1st),(pitch
    of 1st),(No. of times),(length
    of 2nd),(pitch of 2nd),(No.of
    times)....up to....(length
    of 8th),(pitch of 8th),(No.of
    times)
20  FOR a=23300 TO 23323:
    READ d:POKE a,d: NEXT a
```

The length of each beep is a number from 1 to 255 and the longest note is 0. The pitch of each beep is a number from 1 to 255 where 1 is the highest pitch (but 0 is the lowest). Similarly the multiplier (how many times) goes from 1 to 255 (again 0 gives 256 cycles).

This program as it stands resides in the printer buffer which for most people is unused. However if you enter any of the printer commands: LLIST, LPRINT or COPY then the sound will generate a delay followed by NEW, so take care.

Once you have provided the machine with the data you will need to know how to play the sounds. For this there are two commands:

```
LET  (an unused variable)=USR
     23410 this will play your
     sound with tones
LET  (an unused variable)=USR
     23432 this will play your
     sound with white noise.
```

Another slight snag encountered with this routine is that when the sounds are produced the border goes white. If you use an assembler to write in this programm you can change it to suit your needs.

HINTS

It is a wise idea to make the sounds last for as short as possible because it is then less obvious that the program stops to produce the sound. Also, the volume of the sounds is increased by resting the machine on a hard flat surface such as a desk or table.

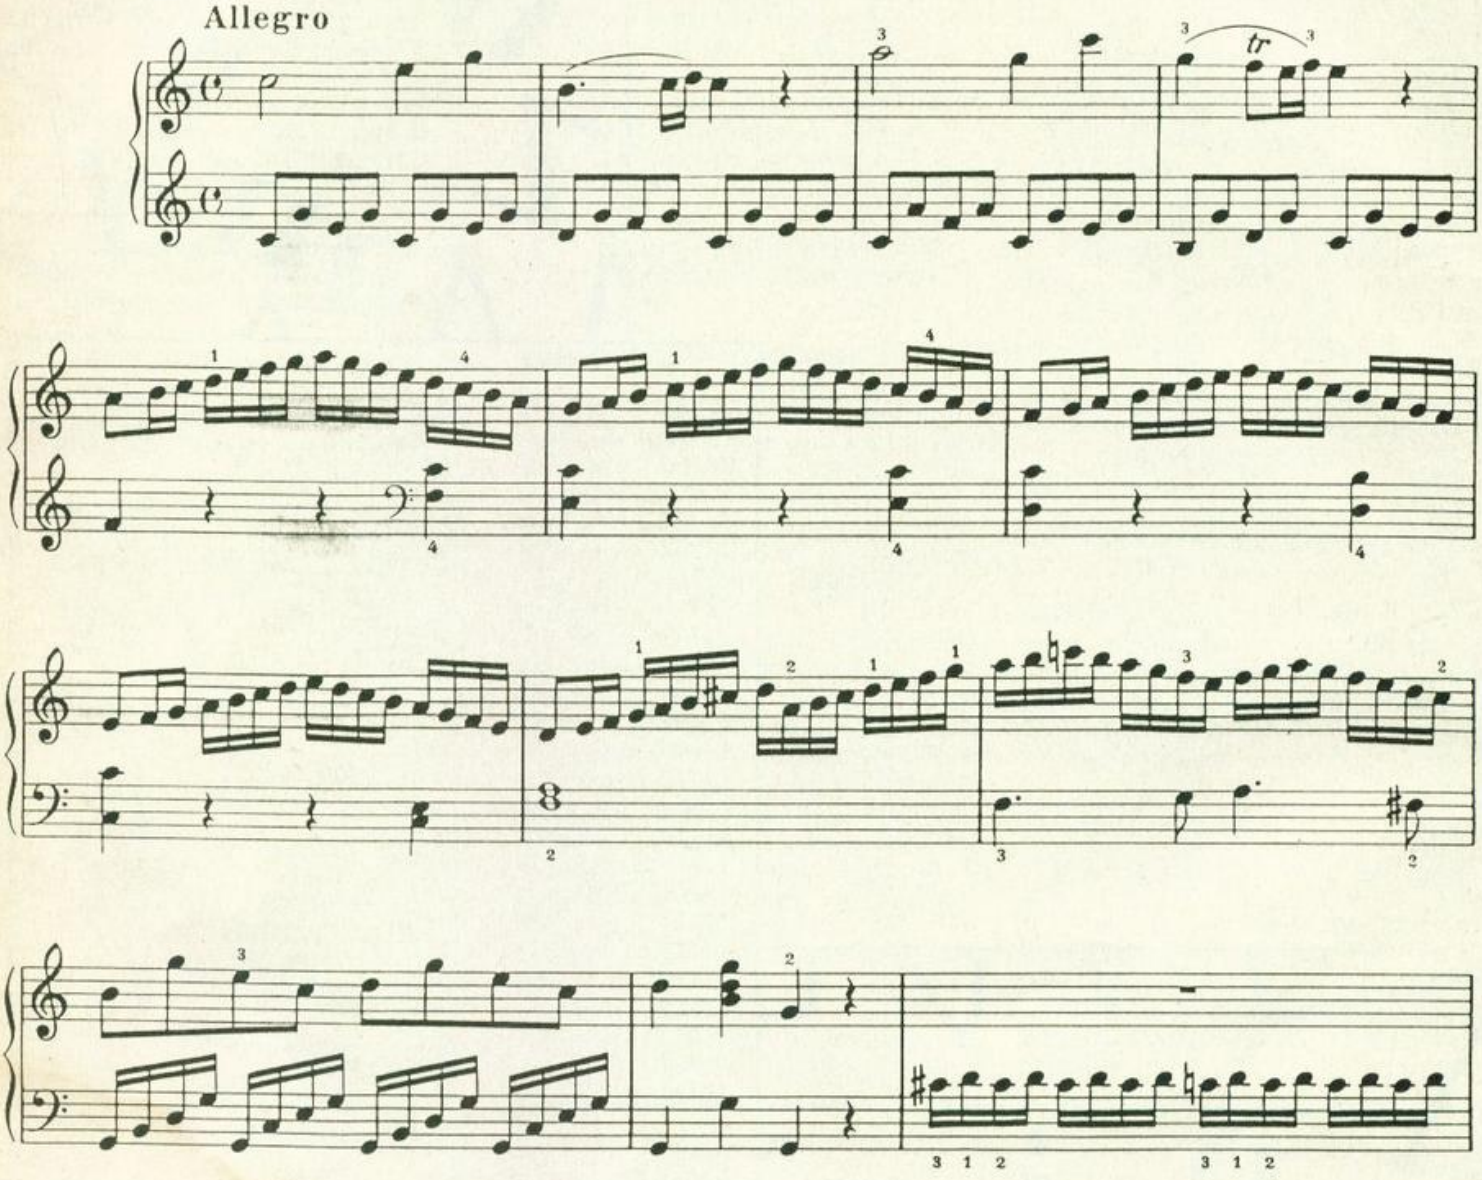
CHI-YEUNG CHOY

From beep to Mozart

And you thought all your Spectrum could do was beep quietly at you! Think again, music lovers.



The Spectrum's oft maligned beep has been considered too feeble for any reasonable musical application in the past, but now we present a program which will make you think again!

Instead of the usual selection of sound effects or brief burst of barely recognisable tunes, Chi-Yeung has successfully programmed a computer version of the first movement of Mozart's piano sonata in C Major K545. What is even more amazing is that it is written all in BASIC and fits into the 16K machine!

ANDANTE

A great deal of thought and attention to technical detail has gone into this program for instance, the subroutines have been put at the start of the program to get every ounce of speed from the computer.

Chi-Yeung tells us that his greatest problem was fitting it into the 16K due to the amount of DATA required and that he almost gave up. Type it in and then give your fingers a rest and your ears a treat. Play on maestro!

HOW IT RUNS

Lines 30-230	*Subroutines.*
Lines 240-520	*DATA statements containing pitch of notes.*
Line 1000	*Set up variables for note duration.*
Lines 1010-2070	*Main program consisting of FOR-NEXT loops.*

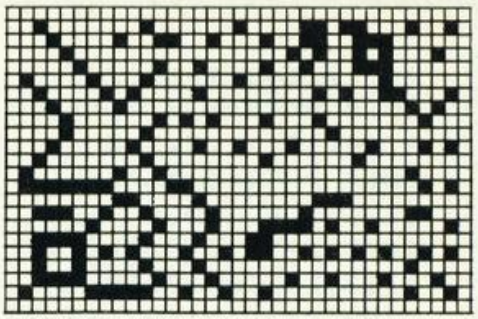
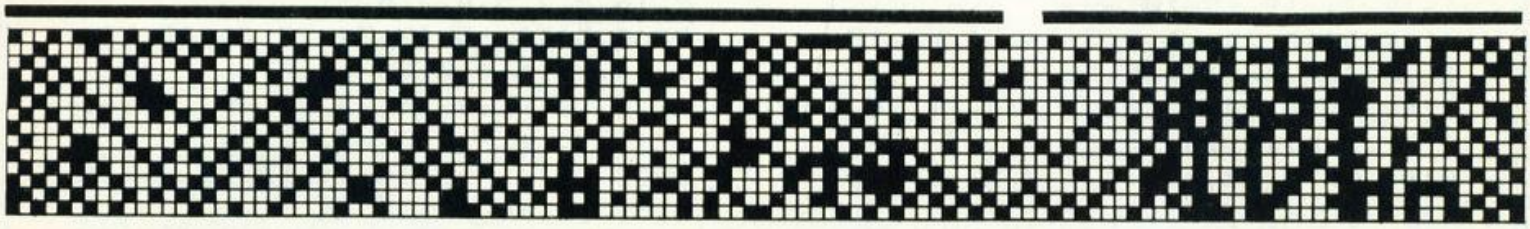
Transforming graphic characters



Speed up the creation of characters by letting your computer do all the hard work



Most home computer programmers find that at some stage there is a need to use larger graphics characters built up from a number of individual user defined graphic characters. We may also need to use the same large character, but facing in a different direction. This program will considerably reduce the time and effort needed in calculating the required POKE values.

To illustrate the use of the program we will go through the steps needed to create a 2x2 character representing a small aeroplane which can be displayed on the screen facing in four different directions. This involves calculating the DATA for 16 user defined characters; a total of 128 POKE values. Using the program we only need to define two characters with a total of 16 POKE values.

The computer will calculate the rest.

MAKING IT PLAIN

In Fig. 1 you will see half the outline of the aeroplane and the DATA values which must be calculated to generate these characters. These values have been included in the program as lines 9000 and 9010. Also by entering GOTO 8970 in the direct addressing mode, these two characters will be POKEd into the UDG areas 'A' and 'B'.

Since the full character is symmetrical about its longitudinal axis, a reflection in the vertical plane (i.e. the right hand edge of each character) will produce the two characters needed to complete the character. To do this RUN the program and select option 1 from the menu.

When asked for the line number, enter 9000. The old values (i.e. line 9000) will be displayed together with the new DATA values. You will now be asked to choose which graphics character you would like the values

VARIABLES USED

A	*number of DATA line from which values of bytes are to be read*
F	*array to hold new DATA values*
M	*array to hold old DATA values*
B,C,D,E,	*transient variables used to hold values during calculations and whose values may change during a calculation*
G	*value of first address in memory of current UDG character*
H	*variable having a value between 0 and 20 used as a pointer to the chosen UDG character. Value is obtained from ASCII number of letter chosen*
I,J,K,L,	*counters used in FOR...TO...NEXT loops*

HOW IT RUNS

7000-7110	*menu display and option selection*
7120-7220	*vertical reflection routine. Each pixel in each row is read, if used, an appropriate value is added to the row total and the final value stored*
7230-7240	*prints old and new DATA values to screen*
7250-7330	*offers UDG character choice and POKEs values into chosen area of memory*
7340-7400	*offers printer, STOP and return to menu options (note that lines 7230 to 7400 serve all the menu options)*
7410-7450	*horizonal reflection or inversion routine. The values for each row of pixels are re-ordered. Value 1 becomes value 8, value 2 becomes value 7, and so on.*
7460-7590	*rotation through 90 degrees routine. The first pixel in each row is read; if used an appropriate value is added to the variable C; the final value of C then becomes the value of row 1. The process is repeated for the second pixel in each row to obtain a value for row 2 and so on till all eight values have been found*

POKEd into. Press 'C' and then take the STOP option when it is offered. Using the DATA still display on the screen, enter into the program 9020 DATA (the values shown without the final comma). Repeat the process again, but this time using initial line number 9010, character 'D' and program data line 9030.

COMBINATIONS

You have now added two lines of data and should have four characters which can be combined to give the shape shown in Fig. 2.

The procedure is the same for menu options 2 and 3, while option 4 allows you to escape from the program.

To invert the aeroplane RUN, choose option 2, repeat procedure four times using lines 9000, 9010, 9020, and 9030 as initial lines; characters 'E', 'F', 'G' and 'H'; and storing the data in program lines 9040, 9050, 9060 and 9070. The four latest characters can now be combined to produce an aeroplane pointing down the screen.

NEVER FORGET YOU HAVE A CHOICE

Finally by RUNing, choosing option 3, using lines 9000 to 9070 as initial lines, POKEing characters 'I' to 'P' and storing the data in program lines 9080 to 9150, you will have the remaining eight characters needed to display the areoplane facing left and right.

The whole process takes much longer to describe than to perform and half an hour's practice and experimentation should put you in command of a most useful programming aid.

The line numbering has been chosen to occupy an area which will not often be used when writing your own programs. This means that the program can be loaded before you start to write. You should replace lines 9000 and 9010 with your own data.

If you don't want to delete the program when you have written your own program it is advisable to include a line such as _6999 STOP or 6999 GOTO (the last line number of your program).

An option to record the old and new DATA by means of a printer is also included.

The program can also be used to transform nonsymmetric characters, but you may have to combine a number of reflections and rotations (holding the DATA in intermediate line numbers) before the desired orientation is obtained.

Compose Yourselves

Write your own music with this program or use it to convert Dragon listings.

This program simulates the Dragon PLAY command by allowing you to enter a string of letters and numerals which are then translated into the Spectrum BEEP commands.

The main variables are as follows: T tempo, O octave, L note length and P pause length. Each let ter is followed by a number, if you don t include them then the follow ing default values are set by the computer:

T2 – roughly equivalent to 4/4 time; O2 – the octave below mid dle C; L4 – gives a note length equivalent to a ¼ note duration. No default value is set for P, but the pauses have the same duration as the note lengths e.g. P8 gives a pause equivalent to the duration of an eighth note. The notes are entered by using the letters A to G.

You can also modify notes by using the relevant symbols for sharps, flats and dotted notes etc.

MUSIC TO CODE

The first part of the program describes the variables and their parameters and shows the normal musical notation and the program equivalents. It should be possible, with a little practice, to translate written music into the program code. The computer translates this into Spectrum BEEPs and displays these on the screen.

As each BEEP is calculated the note is sounded and the pitch and duration values displayed. The tune is played at normal speed and the in formation redisplayed. You can then replay the tune as many times as you wish without losing the informa tion. When you have copied the BEEP values for future use you can return to the menu to enter more music. You can have a printed copy by changing any PRINT commands in lines 1240 to 1280 to LPRINT. If you want a copy of your original str ing entry, then break into the pro gram (CAPS SHIFT and BREAK) and enter the direct addressing mode LPRINT or PRINT A$.

CONVERSIONS

To convert PLAY commands in Dragon listings you select the MUSICMAKER option and enter the strings in the listings. The only variables that are not found in this program will be the letter V follow ed by a number. This controls the volume. There is no volume control on the Spectrum and so these are ig nored.

The other sound command on the Dragon is SOUND. This plays a given note for a given duration and a short program (line 1340 onwards) to deal with this conversion has been included.

10 SECOND LIMIT

The only difficulty that will be en countered is that the Spectrum will not BEEP for longer than 10 seconds. If the second number after SOUND is larger than 160 then sub tract 160 from the value and enter as two separate values. SOUND 90,192 could be entered as SOUND 90,160: SOUND 90,132 translated as BEEP 10,0: BEEP 2,0. If you want to speed the program up by leaving out the BEEPs during the calculation then omit line 1070.

HOW IT RUNS

10-15	*put CAPS LOCK on, directs to graphics routine*
30-50	*MUSICMAKER or SOUND selection routine*
70-225	*menu of instructions, selection routine*
230-355	*details of variables and parameters*
360	*input point for string of variables*
370-440	*set default values for T,O,L*
450-580	*main loop to read input, allocate items in A$ to subroutines*
590-700	*calculation of tempo*
710-810	*calculation of octave start values*
820-930	*calculation of note length*
940-1020	*allocation of relative pitch values to note letters*
1030-1090	*calculation of pitch and duration; first print and sound*
1100-1190	*calculation of pause length*
1200-1230	*play tune at correct speed*
1240-1280	*list Spectrum BEEP values*
1290-1300	*play and list again or return to menu*
1340-1360	*instructions for Dragon SOUND conversion*
1370-1380	*input of Dragon SOUND values*
1390-1400	*conversion calculations*
1410-1420	*display Spectrum values and play sound*
1430-1460	*options for another SOUND conversion or return to menu*
1470-1490	*graphics POKE routine*
1500-1660	*DATA values for graphics characters*

VARIABLES USED

A$	*string holding input variables*
T	*tempo*
O	*octave*
L	*note length*
P	*pause length*
A to G	*note pitch values*
H(K)	*number array holding pitch values*
J(K)	*number array holding values*
K	*note counter*

Error Handling

Sinclair really shouldn't have left the provision of an ON ERROR facility to us.

This article describes a short machine code routine which adds an ON ERROR facility to Spectrum BASIC.

There are many ways in which a program can terminate:

1) Legitimately, by reaching the end of the program or by a STOP statement.
2) By a bug in the program: NEXT without FOR, Out of DATA, etc.
3) By an unforeseen event: Out of memory, Number too big, etc.
4) By an I/O error: STOP in INPUT, Tape loading error, End of file, etc.
5) By the user typing BREAK.

When one of these events occurs, we may want the program to continue running, and possibly take some special action. There are many things that can be done:

a) terminate.
b) ignore the error and carry on regardless.
c) repeat the statement which caused the error.
d) jump to some other statement.
e) perform some statement (or routine) and then return to the interrupt statement.
f) hang up or self destruct.

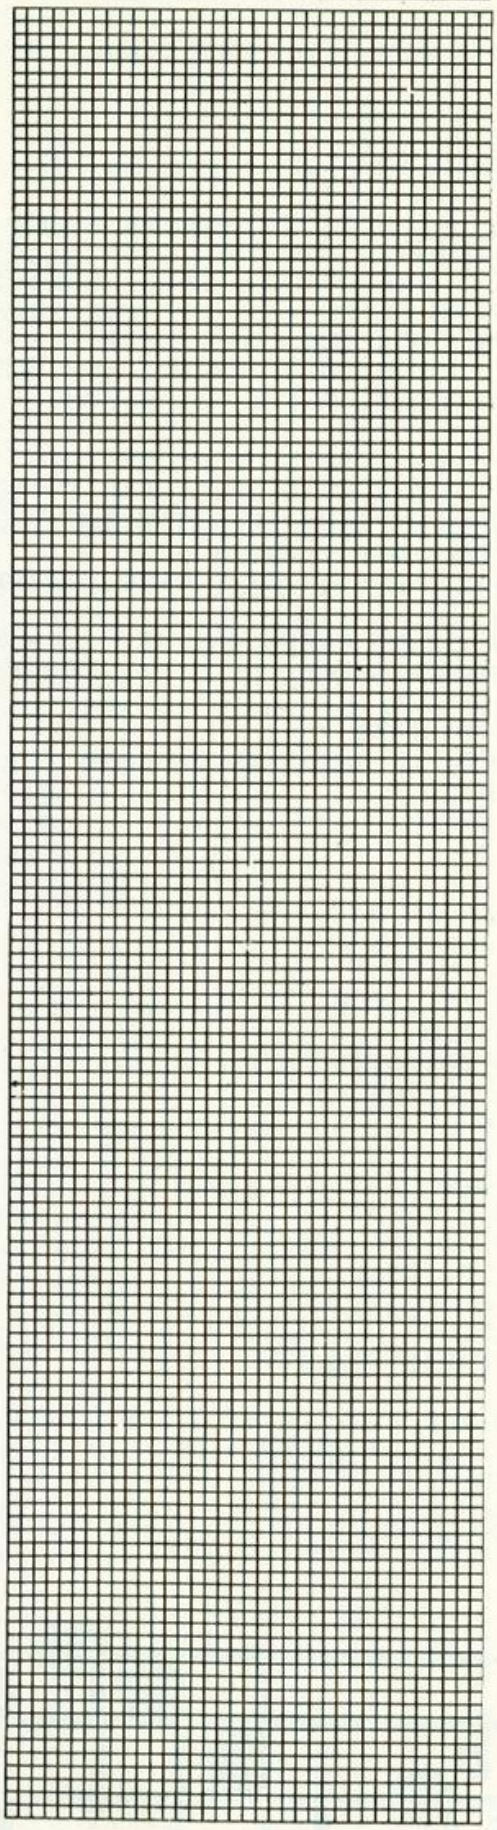
We might want different actions for different errors; eg (b) is suitable for (5) but (d) is more suitable for (3). The only action provided by Spectrum BASIC is of course (a).

THE COMPETITION

Other microcomputers have ON ERROR and ON BREAK statements for specifying the actions to be taken when errors occur. In principle, Interface 1 owners could write a machine code routine to add such statements to the Spectrum. However, the facility described here is accessed via USR, PEEK and POKE; it can be used whether Interface 1 is present or not. The new facility will handle all the errors which have a report number — thus things like "L BREAK" are handled, but note that "Microdrive not present", etc are not.

PROGRAM 1

Program 1 loads a machine code routine into memory. If the checksum is correct you should save the code using:



SAVE — — — CODE 30000,64

The dashes should be replaced with the filename of your choice. The routine is actually relocatable, which is a posh way of saying that it can be placed anywhere in memory. Thus you can load it again by:

CLEAR 59999
LOAD — — — CODE 60000

or whatever.

To turn the error processing on, you simply call the routine, using:

RANDOMIZE USR 30000

30000 is of course replaced by the appropriate address if you've loaded it elsewhere. This would normally be the first statement in the program, for the obvious reason that error processing is turned on before any errors can occur. This implies that you should load the machine code routine before loading the BASIC program.

When error processing is on, the BASIC program is allowed to terminate 'normally', either with "OK" or by a STOP statement. The error processing will be turned off at this point, so if you re-enter the program you'll have to turn the error processing on as before.

An attempt to terminate with any other error report will be caught, so that the BASIC program continues running.

DESIGN CONSIDERATIONS

The routine has been designed to keep the interface with BASIC simple, and also to keep the routine itself simple. It would have been possible — by some suitable POKE statements — to tell the routine such things as the line number to jump to, but this was rejected for simplicity's sake.

Perhaps the most obvious thing which the routine could do is an automatic CONTINUE whenever an error occurs. This would mean for example that BREAK would be ignored, but if you wanted to take some action you could detect that a BREAK had occured either by looking at the keyboard or by PEEKing the variable ERRNR. However, in most cases, CONTINUE repeats the statement which caused the error. If the error was, say, 'Number too big', then the statement would fail again, and the program would hang in a tight loop for ever. And if a VERIFY fails, there's no point redoing the VERIFY unless you also redo the SAVE first.

PROGRAM 1

Implements an ON ERROR facility in Spectrum BASIC. See text.

```
20      CLEAR 29999
30      address=30000
40      LET h$="210f000922b05ceb2a3d5c732372c93a
        3a5c3c2802fe09ca031321445ccb7e280b3a475c3-
        c772a4 55c22425c2100007c32715c220b5c2ab05ce52a4
        25cc39elb"
50      LET sum=0
60      FOR i=1 TO LEN h$ STEP 2
70      LET byte=16*FN d(h$(i))+FN d(h$(i+1))
80      POKE address+(i-1)/2,byte
90      LET sum=sum+byte
100     NEXT i
110     IF sum  5087 THEN PRINT FLASH 1'" "Line 40
        is wrong!!!!"
120     DEF FN d(c$)=CODE c$-(CODE "0" AND
        c$ ="9")-(CODE "a"-10 AND c$>="a")
```

PROGRAM 2

Example of ON ERROR facility. This assumes that the necessary machine code routine is in memory at address 30000.

```
20      RANDOMIZE USR 30000:
        LET errnr=23610:
        LET ok=255:
        LET number too big=5:
        LET stop in input=16:
        LET invalid file name=14:
        LET tape loading error=26
30      PRINT "Setting up array."' "You can't BREAK this"'
        "(try it and see!!)"
40      DIM n(300)
50      FOR i=1 TO 300
60      POKE errnr,ok
70      LET n(i)=1/INT (10*RND)
80      IF PEEK errnr=number too big THEN PRINT
        "overflow"
90      NEXT i
100     REM LOOP
110     POKE errnr,ok
120     INPUT "Enter file name."' "STOP (shift-6)is"' "inef-
        fective..."' LINE f$
130     IF PEEK errnr=stop in input THEN GO TO 110
140     REM END LOOP
150     REM LOOP
160     SAVE f$ DATA n( )
170     IF PEEK errnr=invalid file name THEN STOP
180     PRINT "Now to verify."' "If it fails, the SAVE"'
        "will be repeated,"' "BREAK will get you out."
190     POKE errnr, ok
200     VERIFY f$ DATA n( )
210     IF PEEK errnr=tape loading error THEN GO TO 160
220     REM END LOOP
230     PRINT "Finished"
240     STOP
```

Rather than have a lot of special cases to try and cope with all eventualities, the solution chosen has no special cases — after an error, execution is always resumed at the next statement. For example in:

```
100 LET n=4
110 LET n=1/0
120 PRINT n
```

the division will result in Number too big. The program will not crash, but will resume execution at the PRINT statement. Since statement 110 is not completed, n will still hold its old value, and so 4 will be printed.

WHAT NEXT?

After an error has occured, the system variable ERRNR (one byte at 23610) will hold a value other than 255. ERRNR corresponds to error reports as follows:

ERRNR	REPORT
255	0(OK)
0,1,...,8	1,2,....,9
9,10,....,26	A,B,....,r

ERRNR will hold such a value until the next error occurs, at which point it will be overwritten with the new error number.

If you want to detect when an error occurs, you should first clear any previous error condition by POKEing 255 in the ERRNR. Beware that executing the last statement does not set ERRNR to 255, because it is assumed to still contain the 255 which was put there when the program began execution. The upshot of this is that if some error has occurred and you haven't cleared ERRNR, the program may not be allowed to finish. You are advised to use a STOP statement whenever you want the program to finish since this sets ERRNR to 8 and will always work.

Thus all error types (2) to (5) mentioned earlier are caught, and any of the actions (a) to (f) can be taken by appropriate code in BASIC.

Program 2 gives some examples.

ON ERROR MACHINE CODE

Adds on ERROR facility to Spectrum BASIC. See text.

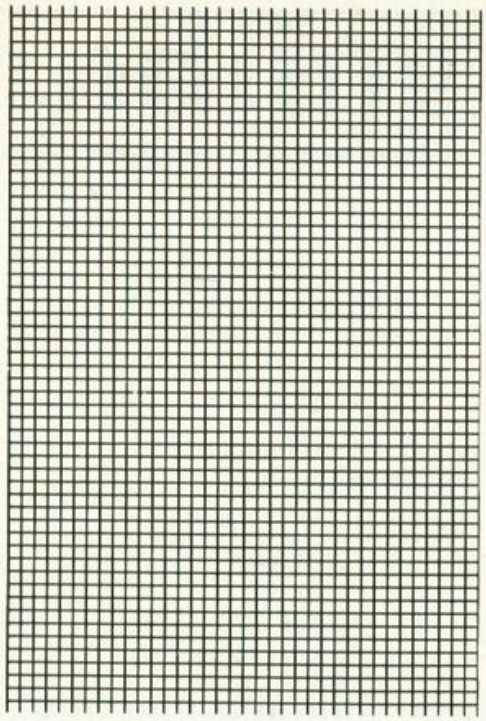
First of all there is a short piece of code to turn on the error processing. This is a matter of working out the address of the <on> label — when this is invoked by USR in BASIC, BC will have the value of <turnon>, and <on> is 15 bytes away — then the address of <on> is stored in two places: an unused location at ▷

UTILITY

23728; and in to the location pointed to by ERRSP...

```
turnon  LD      HL,15
        ADD     HL,BC
        LD      (23728),HL
        EX      DE,HL
        LD      HL,(ERRSP)
        LD      (HL),E
        INC     HL
        LD      (HL),D
        RET
```

The BASIC interpreter may detect any error at all sorts of places. However, the action is always the same (except that is, for errors from Interface 1). The interpreter clears all the junk from the Z80's stack. Since the length of the stack depends on where the error occurred, ERRSP always points to the 2nd value left on the top is an address. Normally it is 1303H; the code at this address prints an error message and prepares to receive a command. The error processing is turned on (above) by changing this address on the stack. Thus when an error occurs, the stack is cleared and our code is involed. For error numbers 0(ok) and 9 (STOP statement) we allow the program to terminate by jumping to the code which was supposed to be executed...



```
on      LD      A,(ERRNR)
        INC     A
        JR      Z,L1
        CP      9
L1      JP      Z,1303H
```

if a jump is about to take place, bit 7 of NSPPC will be 0 — we do nothing. Otherwise, we set up NEWPPC and NSPPC with the line number and statement which is to be executed next (this is one more than the current statement)...

```
        LD      HL,NSPPC
        BIT     7,(HL)
        JR      Z,L2
        LD      A,(SUBPPC)
        INC     A
        LD      (HL),A
        LD      HL,(PPC)
        LD      (NEWPPC),HL
```

now we clear a couple of things which would ordinarily be cleared..

```
L2      LD      HL,0
        LD      A,H
        LD      (FLAGX),A
        LD      (DEFADD),HL
```

finally, the address of our error will have been popped from the stack, so we put it back (remember, we stored it in an unused location)...

```
        LD      HL,(23728)
        PUSH    HL
```

now we jump back in to the interpreter, as if CONTINUE had just been entered, but after the check for BREAK...

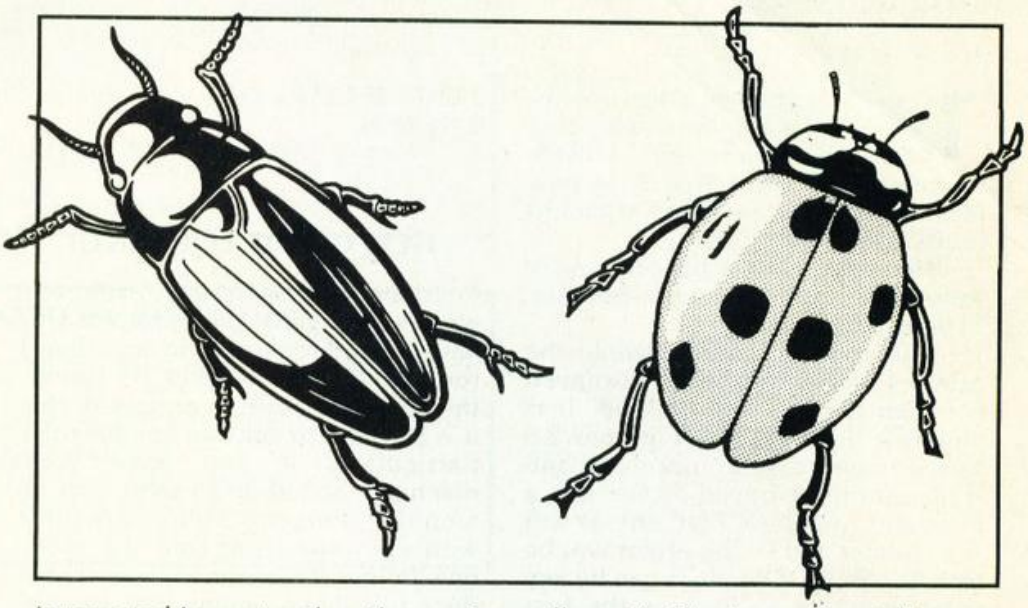
```
        LD      HL,(NEWPPC)
        JP      1B9EH
```

Bugbuster

Careful typist or not, you can still be infested. Who you gonna call? Bugbuster!

Typing in a program is a useful exercise. Apart from the patience required, techniques learned and the end program to be used, probably the most educational part of it is tracking down the bugs introduced by yourself or occasionally by our publication system.

In debugging you gain a much deeper insight and understanding on how the program actually works than by merely typing it in, but tracking down these errors is an art in itself and needs some skill. So here are some tips to help you in your efforts when faced with that cryptic error report!



1 NEXT WITHOUT FOR

Look back through the program. Either the loop has not been set up — no related FOR 'letter' = No1 TO No2 line, or the letter has been reused as an ordinary variable within the loop with a LET 'letter' = No.

2 VARIABLE NOT FOUND

This is one of the most common errors. Again, the problem may not lie in the line where the error was detected and reported. If there is only one variable, which may be one or more letters or a string($) variable, then that is the problem. There may be more than one variable in the line section reported and you will have to identify the offending one. In a line PRINT AT Y,X;A$ the culprit could be Y or X or A$. To find out which of them is causing the problem (it may be more than one) type in turn as a direct command:

PRINT Y Enter/Newline
PRINT X Enter/Newline
PRINT A$ Enter/Newline

Note which produces the error report. Now look back through the program printout for the line which sets it up — usually a LET or FOR command. Did you leave it out? Does the program get there or has a GOTO/GOSUB been wrongly addressed?

3 SUBSCRIPT WRONG

Connected with DIM A(No) or DIM A$(No). If the number in the brackets on the line where the error is reported is greater than the one in the original DIM statement, is not an integer or is less than 1, then this report is generated. If the subscript — number in brackets — is a number then check and change, however, if it is a variable then follow the procedure for tracing variables. It has probably exceeded the limits; look for lines with the variable being altered with + − */: if necessary add limiting code. For example:

IF X >10 THEN LET X=10

4 OUT OF MEMORY

As well as for programs which are too big, it may happen if the previous program set RAMtop. Before despairing, enter CLEAR USR "a"−1.

7 RETURN WITHOUT GOSUB

Somehow the computer has reached a RETURN command other than via a GOSUB instruction. Check a GOTO hasn't been entered in place of a GOSUB. Check for a missing GOSUB.

8 INTEGER OUT OF RANGE

An integer (whole number) either as a number or variable is too big or small and you are attempting to do something like PRINT AT 0,33 — not allowed! Check any variables involved as per report 2 and trace it back through the program looking for adjustments to it by + − */: Add limiting code if needed — see report 3.

9 OUT OF DATA

Check the number of DATA items match the number of READs; usually one (or more) has been missed out. Attempting to reread a DATA list without first using a RESTORE command will cause this and it can happen on an auto start program (saved with a LINE number). Good programming usually RESTOREs to the correct line number before using READ.

10 FOR WITHOUT NEXT

See report 1 but this time the NEXT is missing!

Note that the letters I have used for examples could by ANY letters not just A$,X,Y etc and depend on the particular choice of the programmer.

This is by no means a comprehensive list but I have tried to cover many of the most common error reports. Personally, I get almost as much satisfaction from debugging as I do from programming. I do assure you, however, that there is absolutely no truth in the rumour that we deliberately inject bugs into our listings in order to introduce you to the dubious delights of debugging!

PHILIP CRAWLEY

Supercharger

Hyper short routines to produce mega sound, border and protection tricks for your own crucial programs.

The ZX Spectrum, when released, was at the fore regarding colour, sound and HIRES. However it is clear that it is now lacking in some facilities standard on its contemporaries.

However, with a bit of trickery some nice results are quite feasible. Type in Program 1.

This routine is useful while the rules of a game are being displayed or when a game has finished. It is vital that the code is left at lines 2-6 as the timing is very important, and if the routine is moved deeper into a program, the GOTO (at line 4) will take longer and so the effect will be lost. The BORDER values can be any valid numbers so long as the first two and last two are all equal (1 = blue in this case). Another good border effect can be achieved by changing line 4 to:

```
4 PAUSE 1:IF INKEY$= ""THEN GOTO 3
```

For an explosion using the border try this little routine:

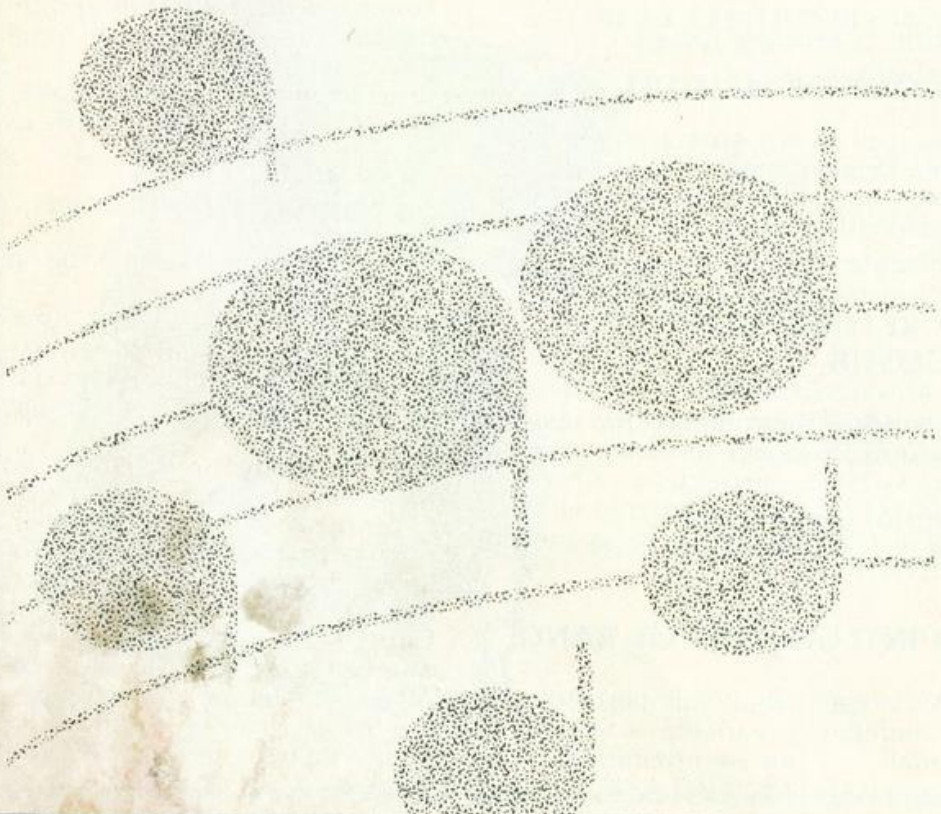
```
1 FOR N=0 TO 100
2 OUT 254,254*RND
3 NEXT N
```

HEY, GOOD LOOKING!

Combine this with any explosion visuals your game contains and you have a good looking (and sounding!) routine. On the subject of sound, the Spectrum is often criticised. But it is possible to achieve good results particularly if you have your machine hooked up to some sort of amplifier. Program 2 plays a rhythm with one tone rising and the other one falling. Programs 3 and 4 produce telephone ringing and a jingle respectively.

Since the BASIC interpreter is lacking in some aspects, several facilities may be implemented via the system or by calls to ROM routines as shown in Tables 1 and 2.

Getting back to the subject of borders try typing in the following line. LET T=USR XXXX where XXXX is an even number between 1310 and 1320. Try all the values as they give different colours.



ANTI-PIRACY DEVICE

If you want to protect your software from piracy the following method works extremely well. Without the use of colour cards or expensive 'dongles' it is possible to make a 48K program copyproof.

Spectrum tape software is usually made up of three distinct parts; short BASIC loader programs, SCREEN$ to keep you amused while the game loads and then machine code. So, to start with lower RAMTOP, load the machine code then enter Program 5. Leave out the normal loader program. It is important that the software is fully de-bugged. Now clear the screen and load your SCREEN$. Then making sure you don't lose the screen, type GOTO 1 and set your tape drive to record.

The principle behind the operation is as follows. No matter what the adverts state, a copier program does require some memory to run it. This may be the printer buffer or the UDG area, but no matter how devious the copier is it is in there somewhere. So if you make a file a full 48K long, it will overwrite the copier program and make it impossible to copy by software means.

The program must be loaded by LOAD ""PROG""CODE and will autorun. Also, the program is altered such that during LOADing, pressing the BREAK key will cause a system reset. Line 3 diables the LIST command so if your program is in BASIC, a measure of extra software protection is provided.

Since the whole of the memory is saved, when the program re-loads, it will take on exactly the same state as it had just after the save procedure. Line 5 disables the break key altogether so it won't crash if the BREAK key is used after loading is complete. Incidentally, if your software is written in BASIC, then Lines 1 and 6 can be omitted. They are, however, vital if your software contains machine code.

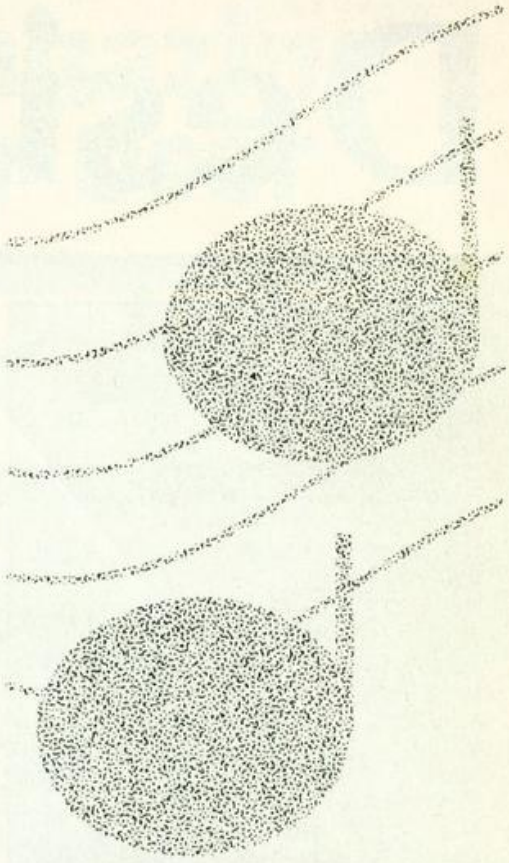
Although this method does increase loading time to five minutes, it is surely worth it when you consider that the software cannot spawn illegal copies. Do your bit for anti-piracy!

TABLE 1 SYSTEM VARIABLES

POKE 237546,0	*— Make line zero out of line 1 — un-editable*
POKE 23658,8	*— CAPS LOCK*
POKE 23658,0	*— CAPS LOCK OFF*
POKE 23755,100	*— Disable LIST command*
POKE 23755,0	*— Re-enables LIST command*
POKE 23659,0	*— 24 line screen, POKE 23659,2 before program finishes*
POKE 23736,181	*— Stops the 'Start tape. . . etc.' prompt*
POKE 23794,181	*— Same, if Interface One is fitted*
POKE 23693,56	*— Resets screen attributes*
POKE 23613,	*— Disable BREAK key*
PEEK (23730)−5	
POKE 23613,0	*— Reset error vector, protects program during LOAD*
POKE 23692,255	*— Disable 'Scroll' prompt*

TABLE 2 CALLS TO ROM ROUTINES

LET T=USR 7997:	*— T is the number of frames before keypress*
LET T=7997-T	
LET T=USR 3582	*— Simulates ZX81 SCROLL function*
LET T=USR 3213	*— Stops and asks 'Scroll'*
LET T=USR 4757	*— Prints Sinclair copyright message*
LET T=65536-USR 7962	*— Number of free bytes*



```
FOR a=1 TO 2:FOR b=11.6 TO 12 STEP 0.1:BEEP .018,b:FOR

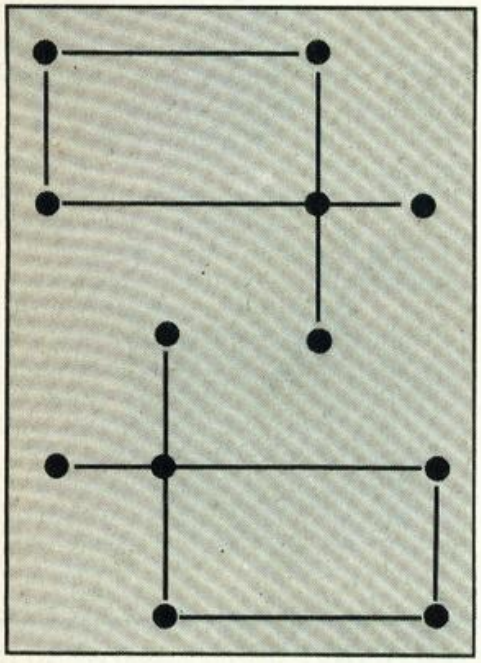
150 REM rest of program
```

```
10 FOR n=0 TO 20
20  BEEP 0.01,n: BEEP 0.01,20-n
30  NEXT n
40  PAUSE 0: RUN
```

Designer

Make the most of your designing ability with this short program.



This program allows you to create designs on your Spectrum using the PLOT, DRAW, and OVER commands.

After specifying the BORDER, PAPER and INK colours, you are invited, through user friendly instructions, to either plot a point, draw a line, or plot and draw over a line (in order to remove any mistakes). It is worth noting that DRAW always draws from the last point plotted, so that if you want a line separate from the last point drawn you must plot a point first.

DRAWBACKS

On this last point, one of the major drawbacks (pun intended) of the DRAW command is that the co-ordinate of the end of the line are offset of the last point plotted. However, it is quite easy to program around this by using the two system variable, bytes 23677 (which holds the y co-ordinate of the last point plotted).

The functions defined in lines 10 and 20 subtract those held in these bytes from the absolute screen co-ordinates you wish to draw to and gives the offset values required by the DRAW command. This method has ramifications for graphics work far beyond the scope of this relatively simple, if enjoyable, program and I hope that you will be able to make good use of it.

```
  10 DEF FN x(a)=a-PEEK 23677
  20 DEF FN y(a)=a-PEEK 23678
  30 BORDER 1: PAPER 1: INK 7: C
